RENESAS MCU

M16C Family / R32C/100 Series

Renesas Electronics
www.renesas.com

Rev.1.20   Sep 2013

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.

2. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.

3. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.

4. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from such alteration, modification, copy or otherwise misappropriation of Renesas Electronics product.

5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

   "Standard":   Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots etc.

   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; and safety equipment etc.

   Renesas Electronics products are neither intended nor authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems, surgical implantations etc.), or may cause serious property damages (nuclear reactor control systems, military equipment etc.). You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application for which it is not intended. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for which the product is not intended by Renesas Electronics.

6. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.

7. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or systems manufactured by you.

8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.

9. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You should not use Renesas Electronics products or technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. When exporting the Renesas Electronics products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations.

10. It is the responsibility of the buyer or distributor of Renesas Electronics products, who distributes, disposes of, or otherwise places the product with a third party, to notify such third party in advance of the contents and conditions set forth in this document, Renesas Electronics assumes no responsibility for any losses incurred by you or third parties as a result of unauthorized use of Renesas Electronics products.

11. This document may not be reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.

12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

(2012.4)

General Precautions in the Handling of MPU/MCU Products

The following usage notes are applicable to all MPU/MCU products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Handling of Unused Pins

   Handle unused pins in accord with the directions given under Handling of Unused Pins in the manual.

   — The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

2. Processing at Power-on

   The state of the product is undefined at the moment when power is supplied.

   — The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.
   In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed.
   In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

3. Prohibition of Access to Reserved Addresses

   Access to reserved addresses is prohibited.

   — The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

4. Clock Signals

   After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

   — When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

5. Differences between Products

   Before changing from one product to another, i.e. to a product with a different part number, confirm that the change will not lead to problems.

   — The characteristics of an MPU or MCU in the same group but having a different part number may differ in terms of the internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

About This Manual

1. Purpose and Target User

This manual is designed to be read primarily by application developers who have an understanding of this microcomputer (MCU) including its hardware functions and electrical characteristics. The user should have a basic understanding of electric circuits, logic circuits and, MCUs.

This manual consists of 30 chapters covering six main categories: Overview, CPU, System Control, Peripherals, Electrical Characteristics, and Usage Notes.

Carefully read all notes in this document prior to use. Notes are found throughout each chapter, at the end of each chapter, and in the dedicated Usage Notes chapter.

The Revision History at the end of this manual summarizes primary modifications and additions to the previous versions. For details, please refer to the relative chapters or sections of this manual.

The R32C/156 Group includes the documents listed below. Verify this manual is the latest version by visiting the Renesas Electronics website.

Type of Document	Contents	Document Name	Document Number
Datasheet	Overview of Hardware and Electrical Characteristics	R32C/156 Group Datasheet	R01DS0075EJ0120
User's Manual: Hardware	Specifications and detailed descriptions of: -pin layout -memory map -peripherals -electrical characteristics -timing characteristics Refer to the Application Manual for peripheral usage.	R32C/156 Group User's Manual: Hardware	This publication
User's Manual: Software/Software Manual	Descriptions of instruction set	R32C/100 Series Software Manual	REJ09B0267-0100
Application Note	-Usages -Applications -Sample programs -Programing technics using Assembly language or C programming language	Available on the Renesas Electronics website.	
Renesas Technical Update	Bulletins on product specifications, documents, etc.		

2.　Numbers and Symbols

The following explains the denotations used in this manual for registers, bits, pins and various numbers.

(1) Registers, bits, and pins
Registers, bits, and pins are indicated by symbols. Each symbol has a register/bit/pin identifier after the symbol.
Example: PM03 bit in the PM0 register
　　　　　P3_5 pin, VCC pin

(2) Numbers
A binary number has the suffix "b" except for a 1-bit value.
A hexadecimal number has the suffix "h".
A decimal number has no suffix.
Example: Binary notation: 11b
　　　　　Hexadecimal notation: EFA0h
　　　　　Decimal notation: 1234

3. Registers

The following illustration describes registers used throughout this manual.

··· Register   *1

Bit Symbol	Bit Name	Function	RW
···0	··· Bit	b2 b1 0 0 : ····· 0 1 : ····· 1 0 : Do not use this combination 1 1 : ·····	RW
···1			RW
— (b2)	No register bit. If necessary, set to 0. When read, the read value is undefined.		—
— (b3)	Reserved	Should be written with 1	RW
— (b4)	Reserved	Should be written with 0 and read as undefined value	RW
···5	··· Bit	Functions vary with operating modes	WO
···6			WO
···7	··· Flag	0: ····· 1: ·····	RO

Symbol ···· Address ···h Reset Value ·····b

*1
Blank box: Set this bit to 0 or 1 according to the function.
0: Set this bit to 0.
1: Set this bit to 1.
X: Nothing is assigned to this bit.

*2
RW: Read and write
RO: Read only
WO: Write only (the read value is undefined)
—: Not applicable

*3
• Reserved bit: This bit field is reserved. Set this bit to a specified value. For RW bits, the written value is
  read unless otherwise noted.

*4
• No register bit(s): No register bit(s) is/are assigned to this field. If necessary, set to 0 for possible future
  implementation.
• Do not use this combination: Proper operation is not guaranteed when this value is set.
• Functions vary with operating modes: Functions vary with peripheral operating modes. Refer to register
  illustrations of the respective mode.

4. Abbreviations and Acronyms

The following acronyms and terms are used throughout this manual.

Abbreviation/Acronym	Meaning
ACIA	Asynchronous Communications Interface Adapter
bps	bits per second
CRC	Cyclic Redundancy Check
DMA	Direct Memory Access
DMAC	Direct Memory Access Controller
GSM	Global System for Mobile Communications
Hi-Z	High Impedance
IEBus	Inter Equipment Bus
I/O	Input/Output
IrDA	Infrared Data Association
LSB	Least Significant Bit
MSB	Most Significant Bit
NC	Non-Connection
PLL	Phase Locked Loop
PWM	Pulse Width Modulation
SIM	Subscriber Identity Module
UART	Universal Asynchronous Receiver/Transmitter
VCO	Voltage Controlled Oscillator

All trademarks and registered trademarks are the property of their respective owners.

TABLE OF CONTENTS

1. Overview

1.1 Features

The M16C Family offers a robust platform of 32-/16-bit CISC microcomputers (MCUs) featuring high ROM code efficiency, extensive EMI/EMS noise immunity, ultra-low power consumption, high-speed processing in actual applications, and numerous and varied integrated peripherals. Extensive device scalability from low- to high-end, featuring a single architecture as well as compatible pin assignments and peripheral functions, provides support for a vast range of application fields.

The R32C/100 Series is a high-end microcontroller series in the M16C Family. With a 4-Gbyte memory space, it achieves maximum code efficiency and high-speed processing with 32-bit CISC architecture, multiplier, multiply-accumulate unit, and floating point unit. The selection from the broadest choice of on-chip peripheral devices — UART, CRC, DMAC, A/D and D/A converters, timers, I^2C-bus interface, and watchdog timer enables to minimize external components.

The R32C/156 Group is the MCU specific to vehicle networks within the R32C/100 Series. This product, provided as 144-pin plastic molded LQFP package, has two channels of CAN module, four channels of LIN module, and standard peripherals.

1.1.1 Applications

Automotive, communication equipment, industrial equipment, etc.

1.1.2   Performance Overview

Tables 1.1 and 1.2 show the performance overview of the R32C/156 Group.

Table 1.1   Performance Overview (1/2)

Unit	Function	Explanation
CPU	Central processing unit	R32C/100 Series CPU Core • Basic instructions: 108 • Minimum instruction execution time: 15.625 ns (f(CPU) = 64 MHz) • Multiplier: 32-bit × 32-bit → 64-bit • Multiply-accumulate unit: 32-bit × 32-bit + 64-bit → 64-bit • IEEE-754 compatible FPU: Single precision • 32-bit barrel shifter • Operating mode: Single-chip mode
Memory		Flash memory: 256/384/512 Kbytes RAM: 20/24/32 Kbytes Data flash: 4 Kbytes × 2 blocks E^2dataFlash: none [1]/4 Kbytes Refer to Table 1.3 for details
Voltage Detector	Low voltage detector	Optional [2] Low voltage detection interrupt
Clock	Clock generator	• 4 circuits (main clock, sub clock, PLL, on-chip oscillator) • Oscillation stop detector: Main clock oscillator stop/restart detection • Frequency divide circuit: Divide-by-2 to divide-by-24 selectable • Low power modes: Wait mode, stop mode
Interrupts		Interrupt vectors: 261 External interrupt inputs: $\overline{NMI}$, $\overline{INT}$ × 9, key input × 4 Interrupt priority levels: 7
Watchdog Timer		15 bits × 1 (selectable input frequency from prescaler output) Automatic timer start function is available
DMA	DMAC	4 channels • Cycle-steal transfer mode • Request sources: 52 • 2 transfer modes: Single transfer, repeat transfer
	DMAC II	• Triggered by an interrupt request of any peripheral • 3 characteristic transfer functions: Immediate data transfer, calculation result transfer, chain transfer
I/O Ports	Programmable I/O ports	• 2 input-only ports • 120 CMOS I/O ports • A pull-up resistor is selectable for every 4 input ports

Timer	Timer A	16-bit timer × 5
		   Timer mode, event counter mode, one-shot timer mode, pulse-width modulation (PWM) mode
		   Two-phase pulse signal processing in event counter mode (two-phase encoder input) × 3

	Timer B	16-bit timer × 6 Timer mode, event counter mode, pulse frequency measurement mode, pulse-width measurement mode
	Three-phase motor control timer	Three-phase motor control timer × 1 (timers A1, A2, A4, and B2 used) 8-bit programmable dead time timer

Notes:

1. Contact a Renesas Electronics sales office to use the non-E^2dataFlash version.
2. Contact a Renesas Electronics sales office to use the optional features.

Table 1.2 Performance Overview (2/2)

Unit	Function	Explanation
Serial Interface	UART0 to UART4	Asynchronous/synchronous serial interface × 5 channels • I^{2}C-bus (UART0 to UART2) • Special mode 2 (UART0 to UART2)
A/D Converter		10-bit resolution × 34 channels Sample and hold functionality integrated Self test/Open-circuit detection assist
D/A Converter		8-bit resolution × 2
CRC Calculator		CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$)
X-Y Converter		16 bits × 16 bits
Intelligent I/O		Time measurement (input capture): 16 bits × 32 Digital debounce circuit contained Waveform generation (output compare): 16 bits × 32 Phase shift waveform output mode contained
Serial Bus Interface		3 channels • Synchronous serial communication mode • 4-wire serial bus mode Programmable character length: 8 to 16 bits
LIN Module		4 channels
CAN Module		2 channels CAN functionality compliant with ISO 11898-1 32 mailboxes
Flash Memory		Programming and erasure supply voltage: VCC = 3.0 to 5.5 V Minimum endurance: 1,000 program/erase cycles Security protection: ROM code protect, ID code protect Debugging: On-chip debug, on-board flash programming
E^{2}dataFlash		Minimum endurance: 100,000 program/erase cycles
Operating Frequency/Supply Voltage		64 MHz/VCC = 3.0 to 5.5 V
Operating Temperature		-40°C to 85°C (J version) -40°C to 105°C (L version) [1] -40°C to 125°C (K version)
Current Consumption		37 mA (VCC = 5.0 V, f(CPU) = 64 MHz) 8 µA (VCC = 3.3 V, f(XCIN) = 32.768 kHz, wait mode)
Package		144-pin plastic molded LQFP (PLQP0144KA-A)

Note:
1. Contact a Renesas Electronics sales office to use the L version products.

1.2 Product Information

Table 1.3 lists the product information and Figure 1.1 shows the details of the part number.

Table 1.3   R32C/156 Group Product List   **As of September, 2013**

Part Number	Package Code [1]	ROM Capacity [2]	RAM Capacity	E^{2}dataFlash	Remarks
R5F64561JFD	PLQP0144KA-A	256 Kbytes + 8 Kbytes	20 Kbytes	4 Kbytes	J Version
R5F64561LFD					L Version [3]
R5F64561KFD					K Version
R5F6456FJFD				NA [3]	J Version
R5F6456FLFD					L Version [3]
R5F6456FKFD					K Version
R5F64562JFD		384 Kbytes + 8 Kbytes	24 Kbytes	4 Kbytes	J Version
R5F64562LFD					L Version [3]
R5F64562KFD					K Version
R5F6456GJFD				NA [3]	J Version
R5F6456GLFD					L Version [3]
R5F6456GKFD					K Version
R5F64563JFD		512 Kbytes + 8 Kbytes	32 Kbytes	4 Kbytes	J Version
R5F64563LFD					L Version [3]
R5F64563KFD					K Version
R5F6456HJFD				NA [3]	J Version
R5F6456HLFD					L Version [3]
R5F6456HKFD					K Version

Notes:
1. The old package code is as follows:
   PLQP0144KA-A: 144P6Q-A
2. "8 Kbytes" in the ROM capacity indicates the data flash capacity.
3. Contact a Renesas Electronics sales office to use the non-E^{2}dataFlash version or the L version products.

1.5   Pin Definitions and Functions

Table 1.8 to Table 1.10 show the pin definitions and functions.

Table 1.8   Pin Definitions and Functions (1/3)

Function	Symbol	I/O	Description
Power supply	VCC, VSS	I	Applicable as follows: VCC = 3.0 to 5.5 V, VSS = 0 V
Analog power supply	AVCC, AVSS	I	Power supply for the A/D converter. AVCC and AVSS should be connected to VCC and VSS, respectively
Connecting pins for decoupling capacitor	VDC0, VDC1	—	A decoupling capacitor for internal voltage should be connected between VDC0 and VDC1
Reset input	$\overline{\text{RESET}}$	I	The MCU is reset when this pin is driven low
CNVSS	CNVSS	I	This pin should be connected to VSS via a resistor
Debug port	NSD	I/O	This pin is to communicate with a debugger. It should be connected to VCC via a resistor of 1 to 4.7 kΩ
Main clock input	XIN	I	Input/output for the main clock oscillator. A crystal, or a ceramic resonator should be connected between pins XIN and XOUT. An external clock should be input at the XIN while leaving the XOUT open
Main clock output	XOUT	O	
Sub clock input	XCIN	I	Input/output for the sub clock oscillator. A crystal oscillator should be connected between pins XCIN and XCOUT. An external clock should be input at the XCIN while leaving the XCOUT open
Sub clock output	XCOUT	O	
Clock output	CLKOUT	O	Output of the clock with the same frequency as low speed clocks, f8, or f32
External interrupt input	$\overline{\text{INT0}}$ to $\overline{\text{INT8}}$	I	Input for external interrupts
NMI input	P8_5/$\overline{\text{NMI}}$	I	Input for NMI
Key input interrupt	$\overline{\text{KI0}}$ to $\overline{\text{KI3}}$	I	Input for the key input interrupt

Table 1.9   Pin Definitions and Functions (2/3)

Function	Symbol	I/O	Description
I/O ports	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7	I/O	I/O ports in CMOS. Each port can be programmed to input or output under the control of the direction register. Pull-up resistors are selected for the following 4-pin units:Pi_0 to Pi_3 and Pi_4 to Pi_7 (i = 0 to 15); however, they are enabled only for the input pins
Input port	P14_1	I	Input port in CMOS. Pull-up resistors are selectable for P14_1 and P14_3
Timer A	TA0OUT to TA4OUT	I/O	Timers A0 to A4 input/output
	TA0IN to TA4IN	I	Timers A0 to A4 input
Timer B	TB0IN to TB5IN	I	Timers B0 to B5 input
Three-phase motor control timer output	U, $\overline{U}$, V, $\overline{V}$, W, $\overline{W}$	O	Three-phase motor control timer output
Serial interface	$\overline{CTS0}$ to $\overline{CTS4}$	I	Handshake input
	$\overline{RTS0}$ to $\overline{RTS4}$	O	Handshake output
	CLK0 to CLK4	I/O	Transmit/receive clock input/output
	RXD0 to RXD4	I	Serial data input
	TXD0 to TXD4	O	Serial data output
I^{2}C-bus (simplified)	SDA0 to SDA2	I/O	Serial data input/output
	SCL0 to SCL2	I/O	Transmit/receive clock input/output
Serial interface special functions	STXD0 to STXD2	O	Serial data output in slave mode
	SRXD0 to SRXD2	I	Serial data input in slave mode
	$\overline{SS0}$ to $\overline{SS2}$	I	Input to control serial interface special functions

Table 1.10   Pin Definitions and Functions (3/3)

Function	Symbol	I/O	Description
A/D converter	AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7	I	Analog input for the A/D converter
	$\overline{\text{ADTRG}}$	I	External trigger input for the A/D converter
	ANEX0	I/O	Expanded analog input for the A/D converter and output in external op-amp connection mode
	ANEX1	I	Expanded analog input for the A/D converter
D/A converter	DA0, DA1	O	Output for the D/A converter
Reference voltage input	VREF	I	Reference voltage input for the A/D converter and D/A converter
Intelligent I/O	IIO0_0 to IIO0_7	I/O	Input/output for Intelligent I/O group 0. Either input capture or output compare is selectable
	IIO1_0 to IIO1_7	I/O	Input/output for Intelligent I/O group 1. Either input capture or output compare is selectable
	IIO2_0 to IIO2_7	I/O	Input/output for Intelligent I/O group 2. Either input capture or output compare is selectable
	IIO3_0 to IIO3_7	I/O	Input/output for Intelligent I/O group 3. Either input capture or output compare is selectable
	UD0A, UD1A, UD0B, UD1B	I	Input for the two-phase encoder
Serial bus interface	SSO0 to SSO2	I/O	Serial data output. Functions as serial data input/output in 4-wire serial bus mode
	SSI0 to SSI2	I/O	Serial data input. Functions as serial data input/output in 4-wire serial bus mode
	SSCK0 to SSCK2	I/O	Transmit/receive clock input/output
	$\overline{\text{SCS0}}$ to $\overline{\text{SCS2}}$	I/O	Input/output to control the synchronous serial interface
LIN module	LIN0OUT to LIN3OUT	O	Transmit data output for the LIN communications
	LIN0IN to LIN3IN	I	Receive data input for the LIN communications
CAN module	CAN0IN, CAN1IN	I	Receive data input for the CAN communications
	CAN0OUT, CAN1OUT	O	Transmit data output for the CAN communications
	$\overline{\text{CAN0WU}}$, $\overline{\text{CAN1WU}}$	I	Input for the CAN wake-up interrupt

2.   Central Processing Unit (CPU)

The CPU contains the registers shown below. There are two register banks each consisting of registers R2R0, R3R1, R6R4, R7R5, A0 to A3, SB, and FB.
Figure 2.1   CPU Registers

2.1   General Purpose Registers

2.1.1   Data Registers (R2R0, R3R1, R6R4, and R7R5)

These 32-bit registers are primarily used for transfers and arithmetic/logic operations.
Each of the registers can be divided into upper and lower 16-bit registers, e.g. R2R0 can be divided into
R2 and R0, R3R1 can be divided into R3 and R1, etc.
Moreover, data registers R2R0 and R3R1 can be divided into four 8-bit data registers: upper (R2H and
R3H), mid-upper (R2L and R3L), mid-lower (R0H and R1H), and lower (R0L and R1L).

2.1.2   Address Registers (A0, A1, A2, and A3)

These 32-bit registers have functions similar to data registers. They are also used for address register
indirect addressing and address register relative addressing.

2.1.3   Static Base Register (SB)

This 32-bit register is used for SB relative addressing.

2.1.4   Frame Base Register (FB)

This 32-bit register is used for FB relative addressing.

2.1.5   Program Counter (PC)

This 32-bit counter indicates the address of the instruction to be executed next.

2.1.6   Interrupt Vector Table Base Register (INTB)

This 32-bit register indicates the start address of a relocatable vector table.

2.1.7   User Stack Pointer (USP) and Interrupt Stack Pointer (ISP)

Two types of 32-bit stack pointers (SPs) are provided: user stack pointer (USP) and interrupt stack
pointer (ISP).
Use the stack pointer select flag (U flag) to select either the user stack pointer (USP) or the interrupt
stack pointer (ISP). The U flag is bit 7 in the flag register (FLG). Refer to 2.1.8 "Flag Register (FLG)" for
details.
To minimize the overhead of interrupt sequence due to less memory access, set the user stack pointer
(USP) or the interrupt stack pointer (ISP) to a multiple of 4.

2.1.8   Flag Register (FLG)

This 32-bit register indicates the CPU status.

2.1.8.1   Carry Flag (C flag)

This flag retains a carry, borrow, or shifted-out bit generated by the arithmetic logic unit (ALU).

2.1.8.2   Debug Flag (D flag)

This flag is only for debugging. Only set this bit to 0.

2.1.8.3   Zero Flag (Z flag)

This flag becomes 1 when the result of an operation is 0; otherwise it is 0.

2.1.8.4   Sign Flag (S flag)

This flag becomes 1 when the result of an operation is a negative value; otherwise it is 0.

2.1.8.5   Register Bank Select Flag (B flag)

This flag selects a register bank. It indicates 0 when register bank 0 is selected, and 1 when register bank 1 is selected.

2.1.8.6   Overflow Flag (O flag)

This flag becomes 1 when the result of an operation overflows; otherwise it is 0.

2.1.8.7   Interrupt Enable Flag (I flag)

This flag enables maskable interrupts. To disable maskable interrupts, set this flag to 0. To enable them, set this flag to 1. When an interrupt is accepted, the flag becomes 0.

2.1.8.8   Stack Pointer Select Flag (U flag)

To select the interrupt stack pointer (ISP), set this flag to 0. To select the user stack pointer (USP), set this flag to 1.

It becomes 0 when a hardware interrupt is accepted or when an INT instruction designated by a software interrupt number from 0 to 127 is executed.

2.1.8.9   Floating-point Underflow Flag (FU flag)

This flag becomes 1 when an underflow occurs in a floating-point operation; otherwise it is 0. It also becomes 1 when the operand contains invalid numbers (subnormal numbers).

2.1.8.10   Floating-point Overflow Flag (FO flag)

This flag becomes 1 when an overflow occurs in a floating-point operation; otherwise it is 0. It also becomes 1 when the operand contains invalid numbers (subnormal numbers).

2.1.8.11   Processor Interrupt Priority Level (IPL)

The processor interrupt priority level (IPL), consisting of 3 bits, selects a processor interrupt priority level from level 0 to 7. An interrupt is enabled when the interrupt request level is higher than the selected IPL.

When the processor interrupt priority level (IPL) is set to 111b (level 7), all interrupts are disabled.

2.1.8.12   Fixed-point Radix Point Designation Bit (DP bit)

This bit designates the radix point. It also specifies which portion of the fixed-point multiplication result to extract. It is used for the MULX instruction.

2.1.8.13   Floating-point Rounding Mode (RND)

The 2-bit floating-point rounding mode selects a rounding mode for floating-point calculation results.

2.1.8.14   Reserved

Only set this bit to 0. The read value is undefined.

2.2   Fast Interrupt Registers

The following three registers are provided to minimize the overhead of the interrupt sequence. Refer to 10.4 "Fast Interrupt" for details.

2.2.1   Save Flag Register (SVF)

This 32-bit register is used to save the flag register when a fast interrupt occurs.

2.2.2   Save PC Register (SVP)

This 32-bit register is used to save the program counter when a fast interrupt occurs.

2.2.3   Vector Register (VCT)

This 32-bit register is used to indicate a jump address when a fast interrupt occurs.

2.3   DMAC-associated Registers

There are seven types of DMAC-associated registers. Refer to 12. "DMAC" for details.

2.3.1   DMA Mode Registers (DMD0, DMD1, DMD2, and DMD3)

These 32-bit registers are used to set DMA transfer mode, bit rate, etc.

2.3.2   DMA Terminal Count Registers (DCT0, DCT1, DCT2, and DCT3)

These 24-bit registers are used to set the number of DMA transfers.

2.3.3   DMA Terminal Count Reload Registers (DCR0, DCR1, DCR2, and DCR3)

These 24-bit registers are used to set the reloaded values for DMA terminal count registers.

2.3.4   DMA Source Address Registers (DSA0, DSA1, DSA2, and DSA3)

These 32-bit registers are used to set DMA source addresses.

2.3.5   DMA Source Address Reload Registers (DSR0, DSR1, DSR2, and DSR3)

These 32-bit registers are used to set the reloaded values for DMA source address registers.

2.3.6   DMA Destination Address Registers (DDA0, DDA1, DDA2, and DDA3)

These 32-bit registers are used to set DMA destination addresses.

2.3.7   DMA Destination Address Reload Registers (DDR0, DDR1, DDR2, and DDR3)

These 32-bit registers are used to set reloaded values for DMA destination address registers.

3.   Memory

Figure 3.1 shows the memory map of the R32C/156 Group.
The R32C/156 Group provides a 4-Gbyte address space from 00000000h to FFFFFFFFh.

The internal ROM is mapped from address FFFFFFFFh in the inferior direction. For example, the 512-Kbyte internal ROM is mapped from FFF80000h to FFFFFFFFh.
The fixed interrupt vector table contains the start address of interrupt handlers and is mapped from FFFFFFDCh to FFFFFFFFh.
The internal RAM is mapped from address 00000400h in the superior direction. For example, the 32-Kbyte internal RAM is mapped from 00000400h to 000083FFh. Besides being used for data storage, the internal RAM functions as a stack(s) for subroutine calls and/or interrupt handlers.

Special function registers (SFRs), which are control registers for peripheral functions, are mapped from 00000000h to 000003FFh, and from 00040000h to 0004FFFFh. Unoccupied SFR locations are reserved, and no access is allowed.
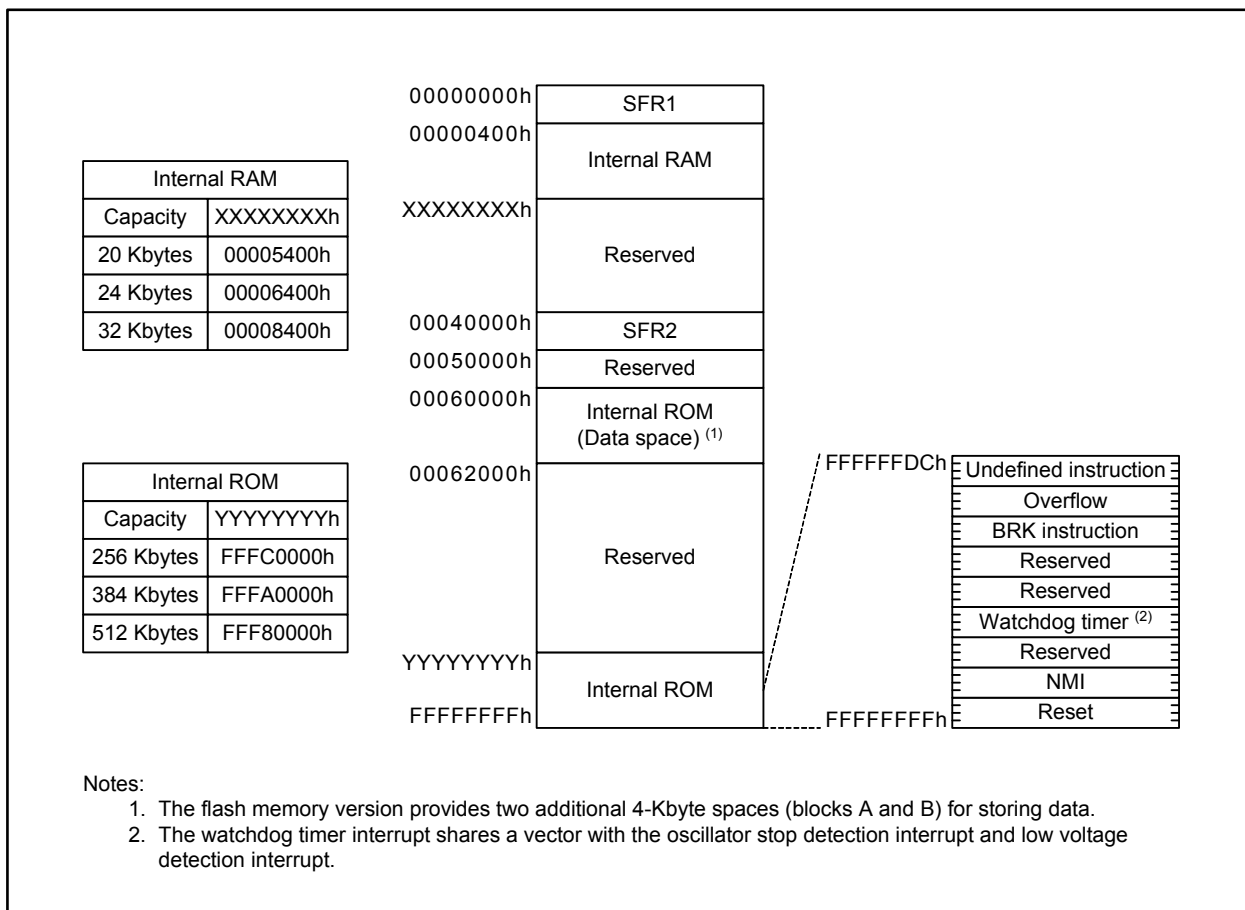

Figure 3.1   Memory Map

4. Special Function Registers (SFRs)

SFRs are memory-mapped peripheral registers that control the operation of peripherals. Table 4.1 SFR List (1) to Table 4.58 SFR List (58) list the SFR details.

5.   Resets

There are three types of operations for resetting the MCU: hardware reset, software reset, and watchdog timer reset.

5.1   Hardware Reset

A hardware reset is generated when a low signal is applied to the $\overline{\text{RESET}}$ pin under the recommended operating conditions of the supply voltage. When the $\overline{\text{RESET}}$ pin is driven low, all pins, and oscillators are reset (refer to Table 5.1 for details), and the main clock starts oscillating. The CPU and SFRs are reset by a low-to-high transition on the $\overline{\text{RESET}}$ pin. Then, the CPU starts executing the program from the address indicated by the reset vector. Internal RAM is not affected by a hardware reset. However, if a hardware reset occurs during a write operation to the internal RAM, the value is undefined.

Figure 5.1 shows an example of the reset circuit. Figure 5.2 shows the reset sequence. Table 5.1 lists pin states while the $\overline{\text{RESET}}$ pin is held low. Figure 5.3 shows CPU register states after a reset. Refer to 4. "Special Function Registers (SFRs)" for details on the states of SFRs after a reset.

A. Reset when the supply voltage is stable

   (1) Drive the $\overline{\text{RESET}}$ pin low.
   (2) Input at least 20 clock cycles to the XIN pin.
   (3) Drive the $\overline{\text{RESET}}$ pin high.

B. Reset when turning on the power

   (1) Drive the $\overline{\text{RESET}}$ pin low.
   (2) Raise the supply voltage to the recommended operating voltage.
   (3) Wait td(P-R) ms until the internal voltage is stabilized.
   (4) Input at least 20 clock cycles to the XIN pin.
   (5) Drive the $\overline{\text{RESET}}$ pin high.
Figure 5.1   Reset Circuitry
Figure 5.2   Reset Sequence

Table 5.1   Pin States while RESET Pin is Held Low [1]

Pin Name	Pin States
P0 to P15	Input port (high-impedance)

Note:
1.   Whether a pull-up resistor is enabled or not is undefined until the internal voltage has stabilized.
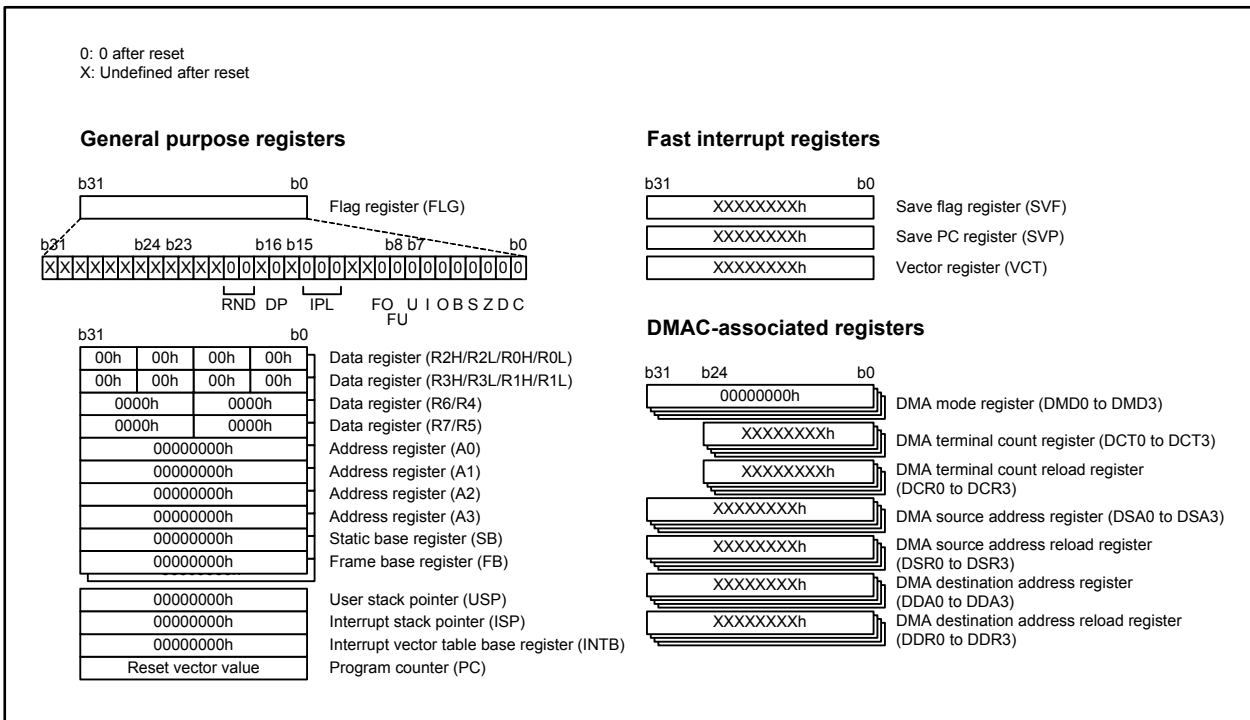

Figure 5.3   CPU Registers after Reset

5.2   Software Reset

The CPU, SFRs, and pins are reset when the PM03 bit in the PM0 register is set to 1 (the MCU is reset). Then, the CPU executes the program from the address indicated by the reset vector. Figure 5.4 shows the PM0 register.

Set the PM03 bit to 1 while the PLL clock is selected as the CPU clock source and the main clock oscillation is completely stable.

Processor Mode Register 0 [1]

b7 b6 b5 b4 b3 b2 b1 b0

| 1 | 0 | 0 | 0 | | 0 | 0 | 0 |

Symbol	Address	Reset Value
PM0	40044h	1000 0000b

Bit Symbol	Bit Name	Function	RW
— (b2-b0)	Reserved	Should be written with 0	RW
PM03	Software Reset Bit	The MCU is reset when this bit is set to 1. The bit is read as 0	RW
— (b6-b4)	Reserved	Should be written with 0	RW
— (b7)	Reserved	Should be written with 1	RW

Note:
1. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.

Figure 5.4   PM0 Register

5.3   Watchdog Timer Reset

The CPU, SFRs, and pins are reset when the watchdog timer underflows while the CM06 bit in the CM0 register is 1 (reset when watchdog timer underflows). Then, the CPU executes the program from the address indicated by the reset vector.

5.4   Reset Vector

The reset vector in the R32C/100 Series is configured as shown in Figure 5.5.
The start address of a program consists of the upper 30 bits of the reset vector and 00b as lower 2 bits.
The lower 2 bits of the reset vector are bits to select the external bus width in microprocessor mode.
Therefore, the start address of a program requires 4-byte alignment so that the lower 2 bits are 00b.
In single-chip mode, set the external bus width select bits to 00b.
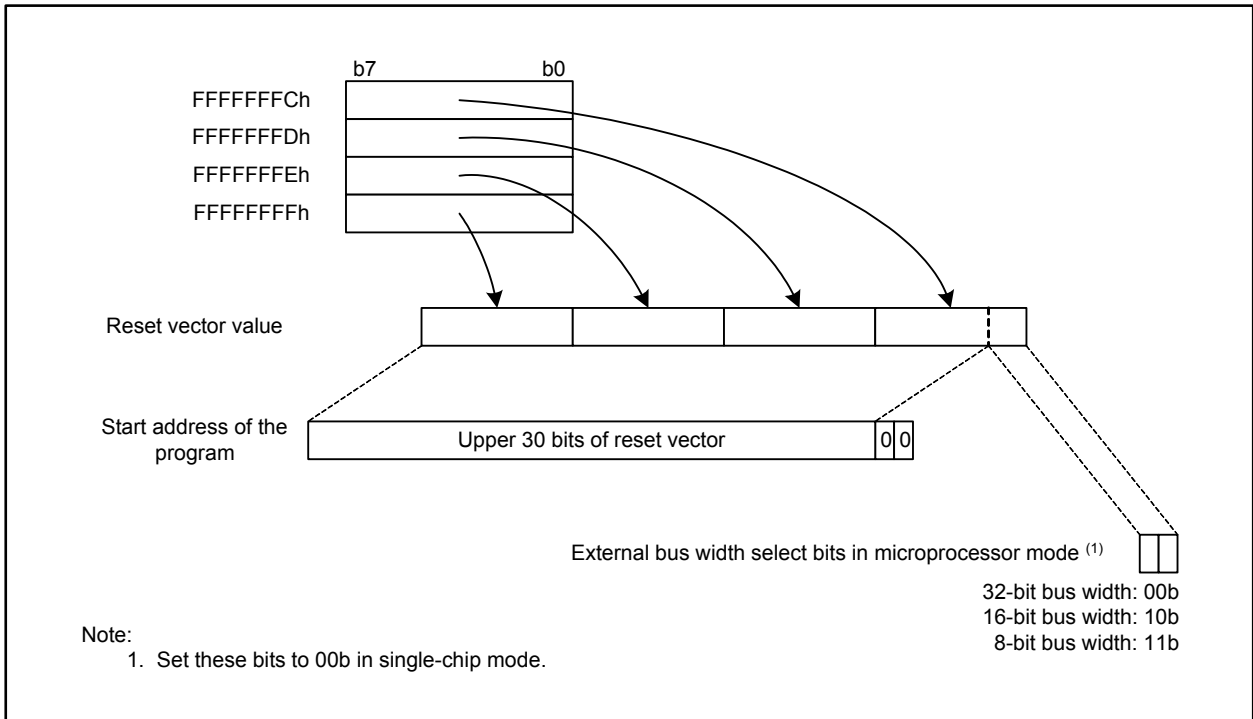

Figure 5.5   Reset Vector Configuration

6.   Power Management

6.1   Voltage Regulators for Internal Logic

The supply voltage for internal logic is generated by reducing the input voltage from the VCC pin with the voltage regulators. Figure 6.1 shows a block diagram of the voltage regulators for internal logic, and Figure 6.2 shows the VRCR register.
Figure 6.1   Block Diagram of Voltage Regulators for Internal Logic
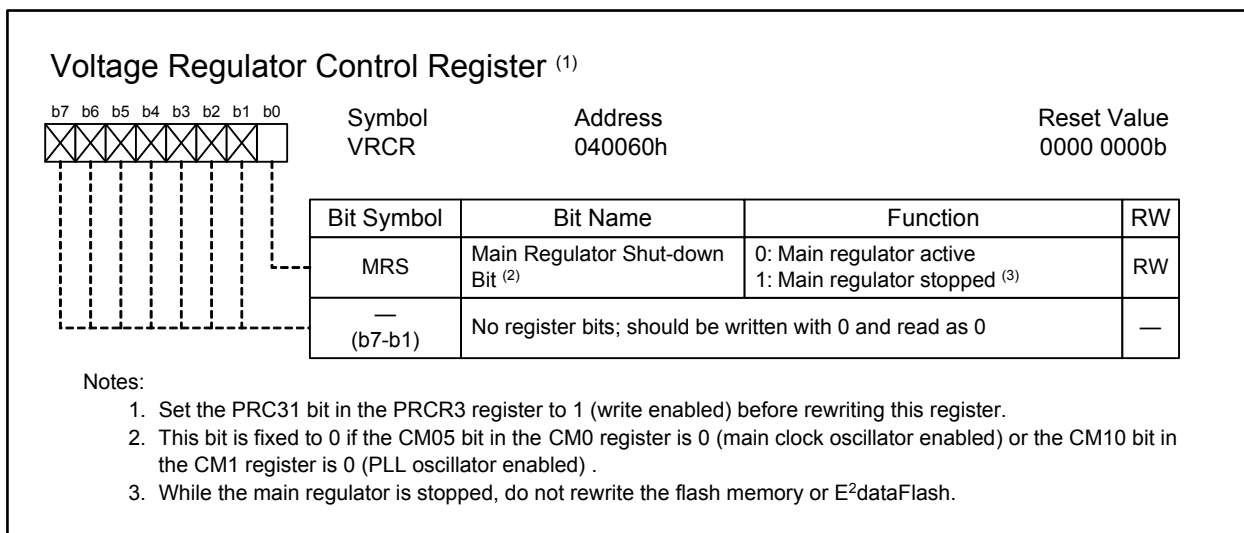

Figure 6.2   VRCR Register

6.1.1   Decoupling Capacitor

An external decoupling capacitor is required to stabilize internal voltage. The capacitor should be beneficially effective at higher frequencies and maintain a more stable capacitance irrespective of temperature change. In general, ceramic capacitors are recommended. The capacitance varies by conditions such as operating temperature, DC bias, and aging. To select an appropriate capacitor, these conditions should be considered. Also, refer to the recommended capacitor specifications listed in Table 6.1.

The traces between the capacitor and the VDC1/VDC0 pins should be as short and wide as physically possible.

Table 6.1   Recommended Capacitor Specifications

Temperature Characteristics			Rated Voltage (V)	Nominal Capacitance (µF)	Capacitance Tolerance (%)
Applicable standard		Operating temperature range (°C)	Capacitance change (%)		
B	JIS	-25 to 85	±10	6.3 or higher	4.7	±20 or better
R	JIS	-55 to 125	±15	6.3 or higher	4.7	±20 or better
X5R	EIA	-55 to 85	±15	6.3 or higher	4.7	±20 or better
X7R	EIA	-55 to 125	±15	6.3 or higher	4.7	±20 or better
X8R	EIA	-55 to 150	±15	6.3 or higher	4.7	±20 or better
X6S	EIA	-55 to 105	±22	6.3 or higher	4.7	±20 or better
X7S	EIA	-55 to 125	±22	6.3 or higher	4.7	±20 or better

6.2   Low Voltage Detector

The low voltage detector monitors the supply voltage input to the VCC pin.
This circuit is used to monitor the power supply upstream of the voltage regulators for internal logic and provide advanced warning that the power is about to fail. By providing a few milliseconds of advanced warning, the CPU can save any critical parameters to the flash memory and safely shut down.
Figure 6.3 shows a block diagram of the low voltage detector, and Figures 6.4 and 6.5 show registers associated with the circuit.

Figure 6.3   Low Voltage Detector Block Diagram

Low Voltage Detector Control Register [1]

b7 b6 b5 b4 b3 b2 b1 b0

Symbol   Address   Reset Value
LVDC   40062h   0000 XX00b

Bit Symbol	Bit Name	Function	RW
VDEN	Low Voltage Detector Enable Bit	0: Low voltage detector disabled 1: Low voltage detector enabled	RW
LVDIEN	Low Voltage Detection Interrupt Enable Bit [2]	0: Interrupt disabled 1: Interrupt enabled	RW
LVDF	Low Voltage Detection Flag [3, 4]	0: Low voltage undetected 1: Low voltage detected (Vdet passed)	RW
VMF	Voltage Monitor Flag [3]	0: VCC < Vdet 1: VCC $\geq$ Vdet or low voltage detector disabled	RO
— (b7-b4)	No register bits; should be written with 0 and read as 0		—

Notes:
1. Set the PRC31 bit in the PRCR3 register to 1 (write enabled) before rewriting this register.
2. Before setting this bit to 1, set the VDEN bit to 1 first, and wait until the circuit is stabilized.
3. This bit is enabled when the VDEN bit is set to 1.
4. This bit can be set to 0 by a program (Writing 1 to this bit has no effect).

3.75 V	3.65 V	3.87 V
3.60 V	3.50 V	3.72 V
3.45 V	3.35 V	3.57 V
3.30 V	3.20 V	3.42 V

Figure 6.5   DVCR Register

6.2.1 Operational State of Low Voltage Detector

The low voltage detector starts operating stably after td(E-A) when the VDEN bit in the LVDC register is set to 1 (low voltage detector enabled).

When the input voltage to the VCC pin drops below Vdet(F), the VMF bit becomes 0 (VCC < Vdet) and the LVDF bit becomes 1 (low voltage detected (Vdet passed)). At this point an interrupt request is generated when the LVDIEN bit is 1 (low voltage detection interrupt enabled). Set the LVDF bit to 0 (low voltage undetected) by a program.

When the voltage rises to or above Vdet(R) again, the VMF bit becomes 1 (VCC ≥ Vdet) and the LVDF bit becomes 1. At this point an interrupt request is generated when the LVDIEN bit is 1.

Figure 6.6 shows the operation of the low voltage detector.
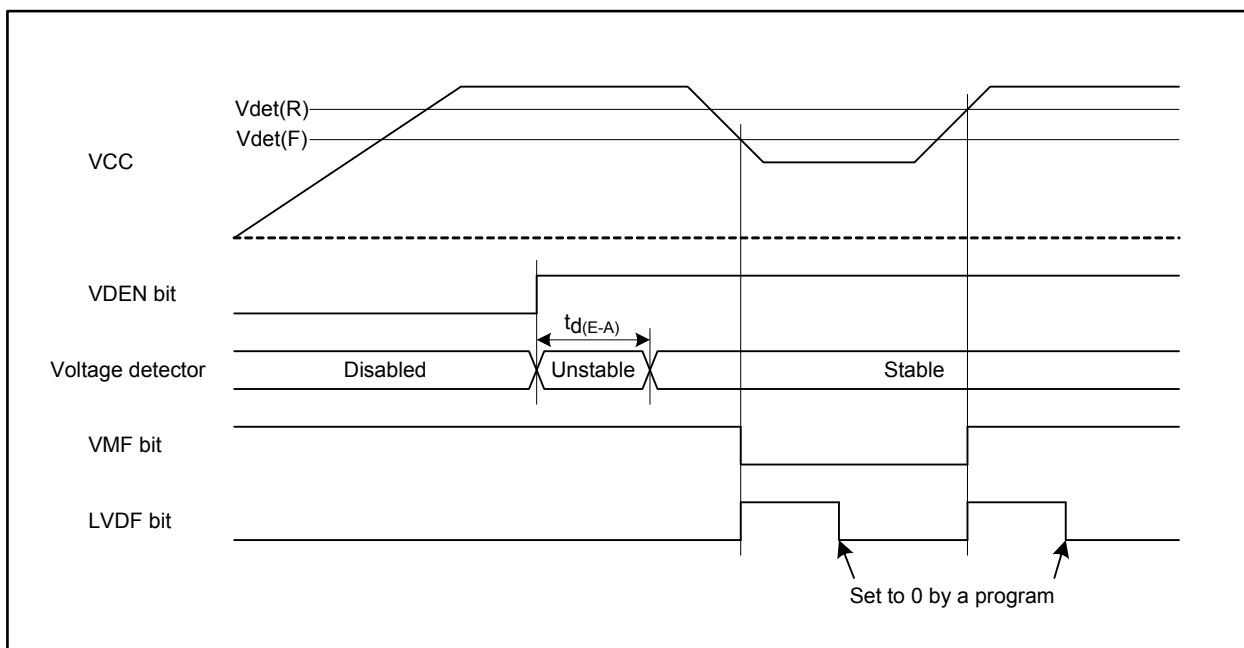

Figure 6.6 Low Voltage Detector Operation

6.2.2 Low Voltage Detection Interrupt

A low voltage detection interrupt request is generated when the input voltage at the VCC pin rises to or above the Vdet(R) level, or falls below the Vdet(F) level while the LVDIEN bit in the LVDC register is 1 (low voltage detection interrupt enabled).

This interrupt shares the interrupt vector with the watchdog timer interrupt and oscillator stop detection interrupt. When using the low voltage detection interrupt with these interrupts at the same time, read the LVDF bit in the LVDC register in the interrupt handler and confirm that the low voltage detection interrupt has been occurred.

The LVDF bit becomes 1 when the input voltage at the VCC pin passes the Vdet(R) level or Vdet(F) level. When the LVDF bit changes from 0 to 1, a low voltage detection interrupt request is generated. Set this bit to 0 (low voltage undetected) by a program.

6.2.3   Application Example of the Low Voltage Detector

Figure 6.7 shows an example of the low voltage detection interrupt.

The supply voltage for internal logic is generated by reducing the input voltage from the VCC pin with the voltage regulators. When the input voltage begins to fall, the internal voltage remains steady. However, as the VCC input voltage continues to fall, the supply voltage for the internal logic also begins to fall, which may affect MCU operation. Consequently, the system can be safely shut down between when the VCC input voltage begins to fall and when the supply voltage for internal logic begins to fall. The low voltage detection interrupt can be applied to detect the falling input voltage.
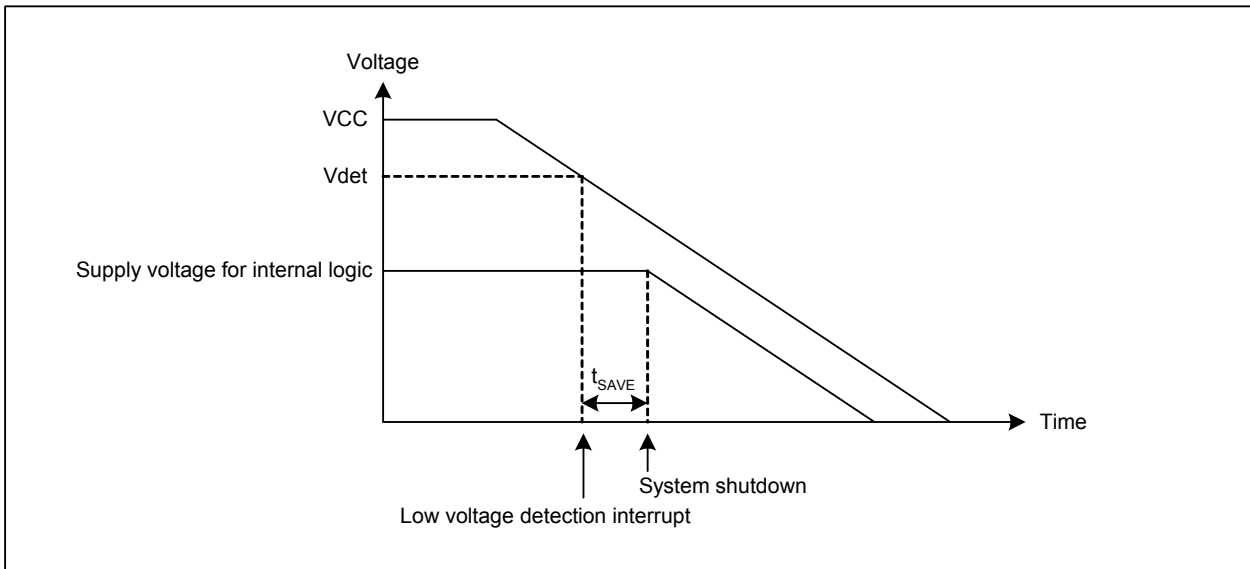

Figure 6.7   Example of the Low Voltage Detection Interrupt

7. Clock Generator

7.1 Clock Generator Types

The clock generator consists of four circuits:
- Main clock oscillator
- Sub clock oscillator
- PLL frequency synthesizer
- On-chip oscillator (OCO)

Table 7.1 lists the specifications of the clock generator. Figure 7.1 shows a block diagram of the clock generator, and Figures 7.2 to 7.10 show registers associated with clock control.

Table 7.1   Clock Generator Specifications

Item	Main Clock Oscillator	Sub Clock Oscillator	PLL Frequency Synthesizer	On-chip Oscillator
Used as	• PLL reference clock source • Peripheral clock source	• CPU clock source • Clock source for timers A and B	• CPU clock source • Peripheral clock source	• CPU clock source • Clock source for timers A and B
Clock frequency	4 to 8 MHz	32.768 kHz	$f_{SO(PLL)}$ or $f_{(PLL)}$	Approx. 125 kHz
Connectable oscillators or additional circuits	Ceramic resonator Crystal oscillator	Crystal oscillator	—	—

CCD1			RW
PCD0	Peripheral Bus Clock Divide Ratio Select Bit [2, 3, 4]	b5 b4 0 0 : Do not use this combination 0 1 : Divide-by-2 1 0 : Divide-by-3 1 1 : Divide-by-4	RW
PCD1			RW
— (b6)	Reserved	Should be written with 0	RW
BCS	Base Clock Source Select Bit	0: PLL clock 1: fC, fOCO4, or f256 [5, 6]	RW

Notes:
1. Set the PRR register to AAh (write enabled) before rewriting this register.
2. The divide ratios of the base clock and peripheral bus clock should not be changed simultaneously. Doing so may cause the peripheral bus clock frequency to go over the maximum operating frequency.
3. The divide ratio of the CPU clock should be equal to or lower than that of peripheral bus clock.
4. Set this bit only once after a reset and do not change the setting afterwards. Rewrite the PBC register before rewriting this bit.
5. To set this bit to 1, a 32-bit write access to addresses 0004h to 0007h should be performed.
6. To use these low speed clocks, select one of them by setting bits CM31 and CM30 in the CM3 register and then set the BCS bit to 1.

Figure 7.2   CCR Register

System Clock Control Register 0 [1]

b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value
0	CM0	40046h	0000 1000b

Bit Symbol	Bit Name	Function	RW
CM00	Clock Output Function Select Bit	b1 b0 0 0 : I/O port P5_3 0 1 : Output a low speed clock 1 0 : Output f8 1 1 : Output f32	RW
CM01			RW
CM02	Peripheral Clock Source Stop Bit [2]	0: Peripheral clock source not stopped in wait mode 1: Peripheral clock source stopped in wait mode [3]	RW
CM03	XCIN-XCOUT Drive Strength Select Bit [4]	0: Low 1: High	RW
CM04	Port XC Switch Bit	0: I/O port 1: XCIN-XCOUT oscillator [5]	RW
CM05	Main Clock Oscillator (XIN-XOUT) Stop Bit [2, 6]	0: Main clock oscillator enabled 1: Main clock oscillator disabled	RW
CM06	Watchdog Timer Function Select Bit [7]	0: Watchdog timer interrupt 1: Reset [8]	RW
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. When the PM21 bit in the PM2 register is 1 (clock change disabled), bits CM02 and CM05 cannot be changed by a write access.
3. fC32 and f2n (whose clock source is the main clock) do not stop.
4. When entering stop mode, the CM03 bit becomes 1.
5. To set the CM04 bit to 1, set bits PD8_7 and PD8_6 in the PD8 register to 0 (input), and the PU25 bit in the PUR2 register to 0 (pull-up resistor disabled).
6. This bit stops the main clock when entering low power mode. It cannot detect whether or not the main clock oscillator stops. When this bit is set to 1, the clock applied to the XOUT pin becomes high. Since the on-chip feedback resistor remains connected, the XIN pin is connected to the XOUT pin via the feedback resistor.
7. Set this bit before activating the watchdog timer. When rewriting this bit while the watchdog timer is running, set it immediately after writing to the WDTS register.
8. Once this bit is set to 1, it cannot be set to 0 by a program.

Figure 7.3   CM0 Register

System Clock Control Register 1 [1]

b7 b6 b5 b4 b3 b2 b1 b0				
0 0 0 0 0	Symbol	Address		Reset Value
	CM1	40047h		0010 0000b

Bit Symbol	Bit Name	Function	RW
CM10	PLL Oscillator Stop Bit [2, 3]	0: PLL oscillator enabled 1: PLL oscillator disabled	RW
— (b4-b1)	Reserved	Should be written with 0	RW
CM15	XIN-XOUT Drive Strength Select Bit [4]	0: Low 1: High	RW
— (b7-b6)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. When the BCS bit in the CCR register is 0 (PLL clock selected as base clock source), the PLL frequency synthesizer does not stop oscillating even if the CM10 bit is set to 1.
3. When the PM21 bit in the PM2 register is 1 (clock change disabled), the CM10 bit cannot be changed by a write access.
4. This bit becomes 1 when the main clock is stopped. When setting to 0, rewrite it after the main clock oscillation is fully stabilized.

Figure 7.4   CM1 Register

Oscillator Stop Detection Register [1]

— (b1)	Reserved	Should be written with 0	RW
CM22	Oscillator Stop Detection Flag [4]	0: Main clock oscillator has not been stopped 1: Main clock oscillator stop detected	RW
CM23	Main Clock Monitor Flag [5]	0: Main clock oscillator active 1: Main clock oscillator stopped	RO
— (b7-b4)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. Set this bit to 0 when f256 is selected as the base clock source in low speed mode.
3. When the PM21 bit in the PM2 register is 1 (clock change disabled), the CM20 bit cannot be changed by a write access.
4. When a main clock oscillator stop is detected, this bit becomes 1. It can be set to 0 by a program, however not to 1. When it is set to 0 while the main clock oscillator is stopped, it does not become 1 until the next main clock oscillator stop is detected.
5. After an oscillator stop detection interrupt occurs, read this bit several times to determine the main clock state.

— (b7)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRC1 bit in the PRCR register to 1 (write enabled) before rewriting this register.
2. Once this bit is set to 1, it cannot be set to 0 by a program.
3. When the PM21 bit is set to 1, the following bits cannot be changed by a write access:
   CM02 bit in the CM0 register (the peripheral clock source state in wait mode)
   CM05 bit in the CM0 register (main clock oscillator enabled/disabled)
   CM10 bit in the CM1 register (PLL oscillator enabled/disabled)
   CM20 bit in the CM2 register (oscillator stop detection enabled/disabled)
4. This bit should be set before the watchdog timer activates.
   When the PM22 bit is set to 1, the state changes as follows:
   -On-chip oscillator clock starts running
   -On-chip oscillator clock functions as the count source of the watchdog timer
   -The watchdog timer is not stopped
5. When the PM24 bit is 0, the forced cutoff of the three-phase motor control timers is also disabled.
6. Stop all the peripherals that use f2n before rewriting this bit.

Notes:
1. Set the PRC0 bit in the PRCR register to 1 (write enabled) before rewriting this register. Stop all the peripherals that use fAD, f1, f8, f32, or f2n (when the clock source is the peripheral clock source) to rewrite this register.
2. Select a divide ratio so that the peripheral clock source frequency does not exceed the maximum value specified in the electrical characteristics

Figure 7.10   PM3 Register

The following sections illustrate clocks generated in clock generators.

7.1.1   Main Clock

The main clock is generated by the main clock oscillator. This clock can be a clock source for the PLL reference clock or peripheral clocks. It also functions as an operating clock for the CAN module.
The main clock oscillator is configured with two pins, XIN and XOUT, connected by an oscillator or resonator. The circuit has an on-chip feedback resistor which is separated from the oscillator in stop mode to save power consumption. An external clock can be applied to the XIN pin in this circuit. Figure 7.11 shows an example of a main clock circuit connection.
Circuit constants vary depending on the oscillator. Circuit constants should be set as per the oscillator manufacturer's recommendations.
After a reset, the main clock oscillator is still independently active and disconnected from the PLL frequency synthesizer. A PLL frequency synthesizer self-oscillating clock divided by 12 is provided to the CPU.
Setting the CM05 bit in the CM0 register to 1 (main clock oscillator disabled) enables power-saving. In this case, the clock applied to the XOUT pin becomes high. The XIN pin connected to the XOUT pin by an embedded feedback resistor is also driven high. Do not set the CM05 bit to 1 when an external clock is applied to the XIN pin.
All clocks, including the main clock, stop in stop mode. Refer to 7.7 "Power Control" for details.
Figure 7.11   Main Clock Circuit Connection

7.1.2   Sub Clock (fC)

The sub clock is generated by the sub clock oscillator. This clock can be a clock source for the CPU clock and a count source for timers A and B. It can be output from the CLKOUT pin.

The sub clock oscillator is configured with pins XCIN and XCOUT connected by a crystal oscillator. The circuit has a on-chip feedback resistor which is separated from the oscillator in stop mode to save power consumption. An external clock can be applied to the XCIN pin. Figure 7.12 shows an example of a sub clock circuit connection. Circuit constants vary depending on the oscillator. Circuit constants should be set as per the oscillator manufacturer's recommendations.

After a reset, the sub clock is stopped and the feedback resistor is separated from the oscillator. In order to start the sub clock oscillation, first set bits PD8_6 and PD8_7 in the PD8 register to 0 (input mode), and the PU25 bit in the PUR2 register to 0 (pull-up resistor disabled). Then, set the CM04 bit in the CM0 register to 1 (XCIN-XCOUT oscillator).

To input an external clock to the XCIN pin, set bits PD8_7 and PU25 to 0 and then the CM04 bit to 1. The clock applied to the XCIN pin becomes a clock source for the sub clock.

When the CM3 register is set to 00h (fC) and the BCS bit in the CCR register is set to 1 (fC, fOCO4, or f256) after the sub clock oscillation has stabilized, the sub clock becomes the base clock of the CPU clock and the peripheral bus clock.

All clocks, including the sub clock, stop in stop mode. Refer to 7.7 "Power Control" for details.
Figure 7.12   Sub Clock Circuit Connection

7.1.3   PLL Clock

The PLL clock is generated by the PLL frequency synthesizer based on the main clock. This clock can be a clock source for any clock including the CPU clock and the peripheral clock.

Figure 7.13 shows a block diagram of the PLL frequency synthesizer. Figures 7.14 and 7.15 show registers PLC0 and PLC1, respectively. Figure 7.16 shows the PLS register.
Figure 7.13   PLL Frequency Synthesizer Block Diagram
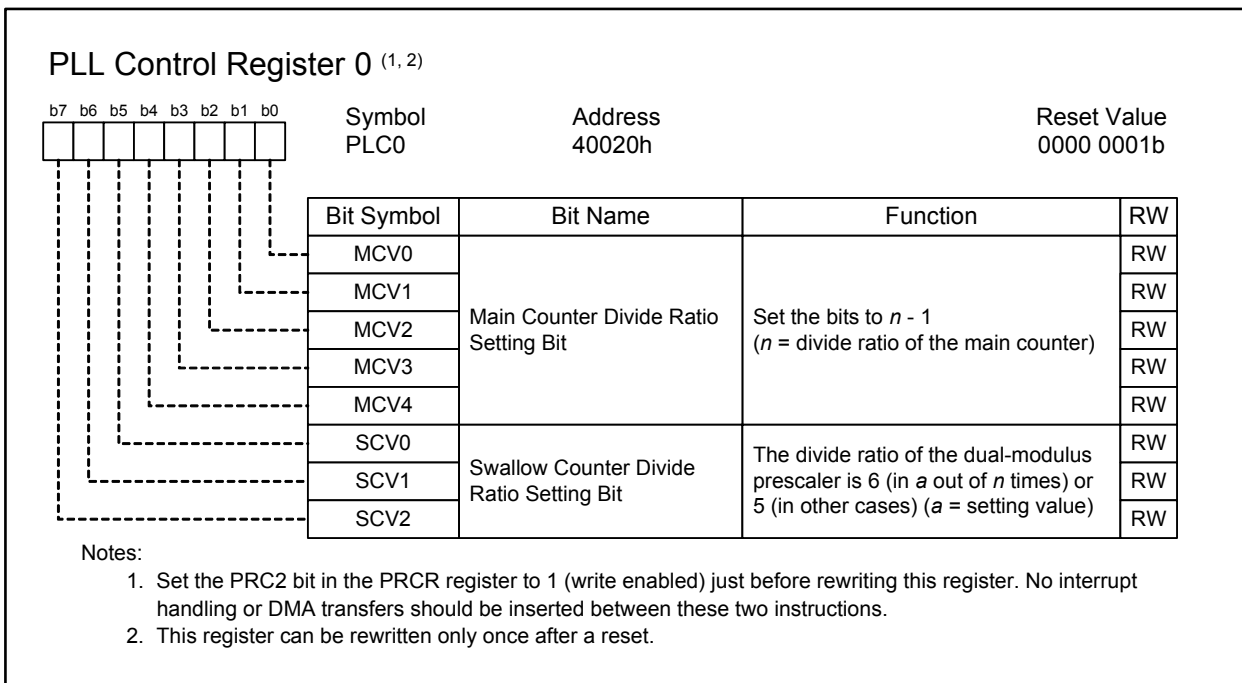

Figure 7.14   PLC0 Register

PLL Control Register 1 [1]

b7	b6	b5	b4	b3	b2	b1	b0

Symbol   Address   Reset Value
PLS   40024h   1XXX XX00b

Bit Symbol	Bit Name	Function	RW
PLF1	PLL Lock Flag 1	PLL output is 0: Out of the specified range 1: Within the specified range	RO
PLF2	PLL Lock Flag 2 [2]	PLL output is 0: Out of the specified range 1: Within the specified range	RO
— (b6-b2)	No register bits; should be written with 0 and read as undefined value		—
PULD	PLL Unlock Detect Flag [3]	0: No unlock detected 1: Unlock detected	RW

Notes:
1. This register is reset after setting the SEO bit in the PLC1 register to 1 (self-oscillating). Stopping the main clock or PLL prevents the register from updating.
2. This bit becomes 1 if the PLF1 bit consecutively becomes 1 twice. If the PLF1 bit becomes 0 twice, the PLF2 bit becomes 0; otherwise it remains unchanged.
3. This bit becomes 1 if the PLF2 bit becomes 0. It becomes 0 by a write access.

Figure 7.16   PLS Register

In the PLL frequency synthesizer, the pulse-swallow operation is implemented. The divide ratio *m* is simply expressed by *n×p*. However, with the swallow counter, the divide ratio *p* is 6 in *a* out of *n*, or 5 in other cases, the actual *m* is therefore given by the formula below:

$$m = n \times p$$

$$= n \times \left(\frac{a}{n} \cdot 6 + \frac{n-a}{n} \cdot 5 \right)$$

$$= 5n + a$$

The setting range of *a* is $0 \le a < 5$, $0 \le a \le n$.

As *r* is the divide ratio of the reference counter, the PLL clock has a *m/r* times the main clock (XIN) frequency.

$$\text{PLL clock frequency } f(PLL) = \frac{m}{r} \cdot \text{main clock frequency}$$

$$= \frac{5n + a}{r} \cdot \text{main clock frequency}$$

After a reset, the reference counter is divided by 16, and the PLL frequency synthesizer is multiplied by 10. Since the main clock as a reference clock is disconnected, the PLL frequency synthesizer may self-oscillate at its own frequency of $f_{SO(PLL)}$.

Each register should be set to meet the following conditions:

-The reference clock, which is the main clock divided by *r*, should be between 2 to 4 MHz.

-The divide ratio *m* is $25 \le m \le 100$.

For the setting of registers PLC1 and PLC0, Table 7.2 should be applied. While the main clock oscillation is stable, a wait time of $t_{LOCK(PLL)}$ is necessary between rewriting registers PLC1 and PLC0, and the PLL clock becoming stable.

Table 7.2   PLC1 and PLC0 Register Settings [1]

Main Clock	*r*	Reference Clock	*n*	*a*	*m*	PLC1 Register Setting	PLC0 Register Setting	*m/r*	PLL Clock
4 MHz	1	4 MHz	6	0	30	00h	05h	30	120 MHz
5 MHz	2	2.5 MHz	9	3	48	01h	68h	24	120 MHz
6 MHz	2	3 MHz	8	0	40	01h	07h	20	120 MHz
8 MHz	2	4 MHz	6	0	30	01h	05h	15	120 MHz
4 MHz	1	4 MHz	6	2	32	00h	45h	32	128 MHz
6 MHz	3	2 MHz	12	4	64	02h	8Bh	21.3333	128 MHz
8 MHz	2	4 MHz	6	2	32	01h	45h	16	128 MHz
4 MHz	1	4 MHz	7	1	36	00h	26h	36	144 MHz
6 MHz	2	3 MHz	9	3	48	01h	68h	24	144 MHz
8 MHz	2	4 MHz	7	1	36	01h	26h	18	144 MHz

Note:
1. Registers PLC1 and PLC0 should be set according to the list above.

7.1.4   On-chip Oscillator Clock

The on-chip oscillator clock is generated by the on-chip oscillator (OCO). This clock can be a clock source for the CPU clock and a count source for timers A and B. This clock has a frequency of approximately 125 kHz. The on-chip oscillator clock divided by 4 can be used as the base clock for the CPU clock and peripheral bus clock.

When the CSPM bit in the OFS area is 1, the on-chip oscillator clock is stopped after a reset. It starts running when setting any of the following bits to 1; the CM31 bit in the CM3 register or the PM22 bit in the PM2 register. It is not necessary to wait for stabilization because the on-chip oscillator instantly starts oscillating.

7.2   Oscillator Stop Detection

This function detects the main clock is stopped when its oscillator stops running due to an external factor. When the CM20 bit in the CM2 register is 1 (enable oscillator stop detection), an oscillator stop detection interrupt request is generated as soon as the main clock stops. Simultaneously, the PLL frequency synthesizer starts to self-oscillate at its own frequency. If the PLL frequency synthesizer is the clock source for CPU clock and peripheral clock, these clocks continue running.

When an oscillator stop is detected, the following bits in the CM2 register become 1:

- The CM22 bit: main clock oscillator stop detected
- The CM23 bit: main clock oscillator stopped

7.2.1   How to Use Oscillator Stop Detection

The oscillator stop detection interrupt shares vectors with the watchdog timer interrupt and the low voltage detection interrupt. When using these interrupts simultaneously, read the CM22 bit with an interrupt handler to determine if an oscillator stop detection interrupt request has been generated.

When the main clock oscillator resumes running after an oscillator stop is detected, the PLL clock frequency may temporarily exceed the preset value before the PLL frequency synthesizer oscillation stabilizes. As soon as an oscillator stop is detected, the main clock oscillator should be stopped from resuming (set the CM05 bit in the CM0 register to 1) or the divide ratios of the base clock and peripheral clock source should be increased by a program. They can be set using bits BCD1 and BCD0 in the CCR register and bits PM36 and PM35 in the PM3 register.

In low speed mode, when the main clock oscillator stops running, an oscillator stop detection interrupt request is generated if the CM20 bit is set to 1 (enable oscillator stop detection). The CPU clock remains running with a low speed clock source. Note that if the base clock is f256, which is the main clock divided by 256, oscillator stop detection cannot be used.

The oscillator stop detection is provided to handle main clock stop caused by external factors. To stop the main clock oscillator by a program, i.e., to enter stop mode or to set the CM05 bit to 1 (main clock oscillator disabled), the CM20 bit in the CM2 register should be set to 0 (disable oscillator stop detection). To enter wait mode, this bit should be also set to 0.

The oscillator stop detection functions depending on the voltage of a capacitor which is being changed. In more concrete terms, this function detects that the oscillator is stopped when the main clock goes lower than approximately 500 kHz. Note that if the CM22 bit is set to 0 by a program in an interrupt handler while the frequency is around 500 kHz, a stack overflow may occur due to multiple interrupt requests.

7.3   Base Clock

The base clock is a reference clock for the CPU clock and peripheral bus clock. The base clock after a reset is the PLL clock divided by 6.

The base clock source is selected between the PLL clock and the low speed clocks which contain the sub clock (fC), on-chip oscillator clock divided by 4 (fOCO4), and main clock divided by 256 (f256).

If the PLL clock is selected, it is divided by 2, 3, 4, or 6 to become the base clock. If a low speed clock is selected, the clock itself can be the base clock.

The base clock source is set using the BCS bit in the CCR register and the divide ratio for the PLL clock is set using bits BCD1 and BCD0. Bits CM31 and CM30 in the CM3 register select a low speed clock.

7.4   CPU Clock and Peripheral Bus Clock

The CPU operating clock is referred to as the CPU clock. The CPU clock after a reset is the base clock divided by 2.

The CPU clock source is the base clock, and its divide ratio is selected by setting bits CCD1 and CCD0 in the CCR register. The base clock divided by 2 to 4 becomes the peripheral bus clock. Its divide ratio is selected by setting bits PCD1 and PCD0 in the CCR register. The peripheral bus clock also functions as a count source for the watchdog timer and operating clock for the serial bus interface and the CAN module. To prevent the CPU clock, whose clock source is the PLL clock, from stopping when the CPU becomes out of control, set the following while the CM05 bit in the CM0 register is 0 (main clock oscillator enabled) and the BCS bit in the CCR register is 0 (PLL clock selected as base clock source):

(1) Set the PRC1 bit in the PRCR register to 1 (write enabled to the PM2 register).
(2) Set the PM21 bit in the PM2 register to 1 (clock change disabled).

7.5   Peripheral Clock

The peripheral clock is an operating clock or a count source for the peripherals excluding the watchdog timer, the serial bus interface, and the CAN module. The source of this clock is generated by a clock, which has the same frequency as the PLL clock, divided by 2, 4, 6, or 8 according to the settings of bits PM36 and PM35 in the PM3 register. The peripheral clock is classified into three types of clock as follows:

(1) f1, f8, f32, f2n

f1, f8, and f32 are the peripheral clock sources divided by 1, 8, and 32, respectively. The clock source for f2n is selected between the peripheral clock source and the main clock by setting the PM26 bit in the PM2 register. The f2n divide ratio can be set using bits CNT3 to CNT0 in the TCSPR register (n = 1 to 15, not divided when n = 0).

f1, f8, f32, and f2n, whose clock source is the peripheral clock source, stop in low power mode or when the CM02 bit is set to 1 (peripheral clock source stopped in wait mode) to enter wait mode.

f1, f8, and f2n are used as a count source for timers A and B or an operating clock for the serial interface and the LIN module. f1 is used as an operating clock for the intelligent I/O as well. The f32 is used as an operating clock for the LIN module as well.

f8 and f32 can be output from the CLKOUT pin. Refer to 7.6 "Clock Output Function" for details.

(2) fAD

fAD, which has the same frequency as peripheral clock source, is an operating clock for the A/D converter.

This clock stops in low power mode or when the CM02 bit is set to 1 (peripheral clock source stopped in wait mode) to enter wait mode.

(3) fC32

fC32, which is a sub clock divided by 32, or on-chip oscillator clock divided by 128, is used as the count source for timers A and B. This clock is available when the sub clock or on-chip oscillator clock is active.

7.6   Clock Output Function

Low speed clocks, f8, and f32 can be output from the CLKOUT pin.
Table 7.3 lists the CLKOUT pin functions.

Table 7.3   CLKOUT Pin Functions

CM0 Register [1]		CLKOUT Pin Function
CM01	CM00	
0	0	I/O port P5_3
0	1	Output a low speed clock
1	0	Output f8
1	1	Output f32

Note:
1.   Set the PRC0 bit in the PRCR register 1 (write enabled) before rewriting this register.

7.7   Power Control

Power control has three modes: wait mode, stop mode, and normal operating mode.

The name "normal operating mode" is used restrictively in this chapter, and it indicates all other modes except wait mode and stop mode. Figure 7.17 shows a block diagram of the state transition in normal operating mode, stop mode, and wait mode.
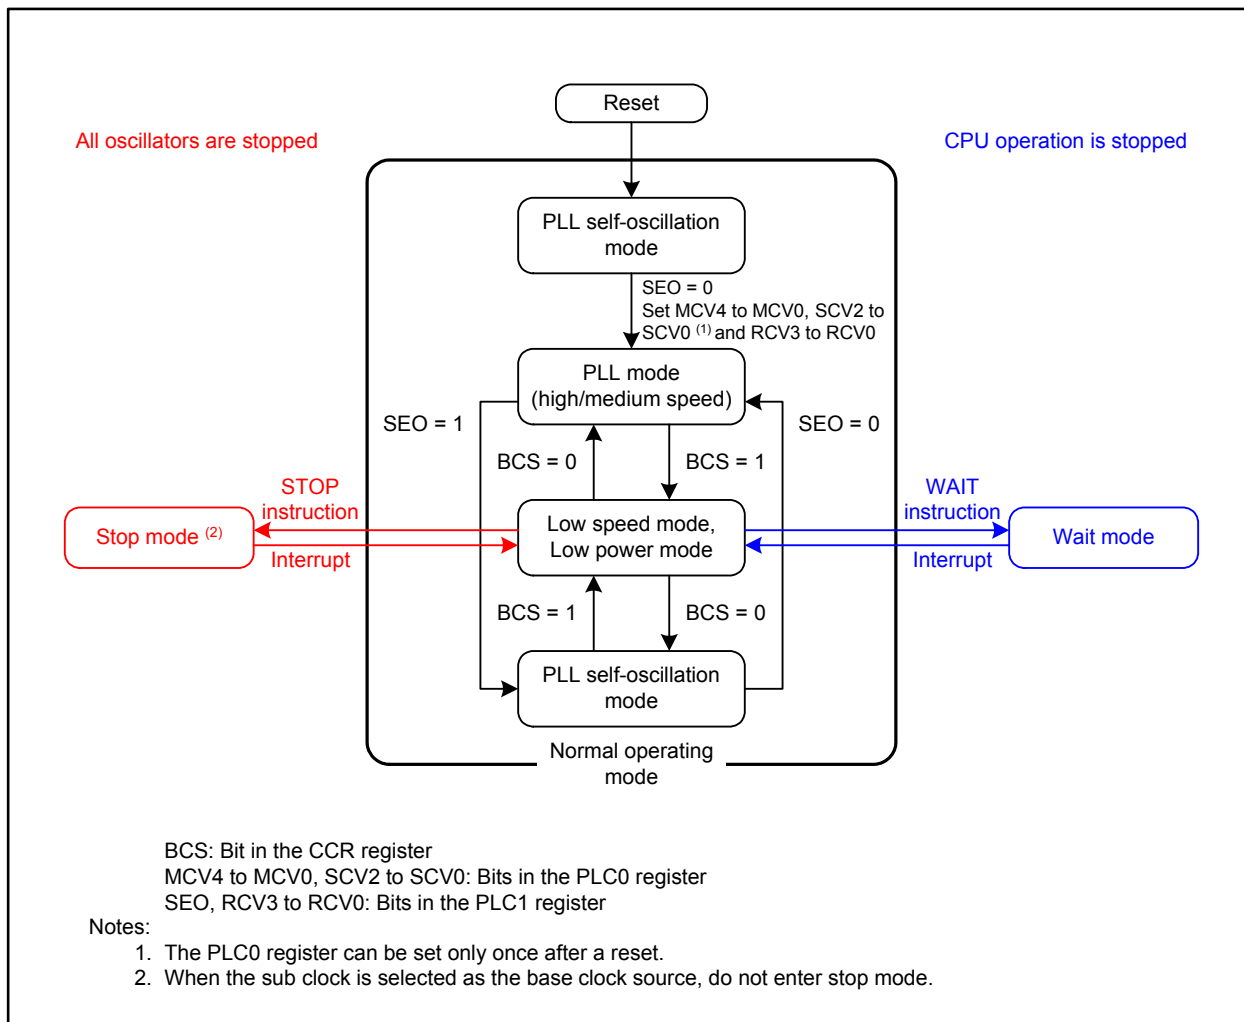

Figure 7.17   State Transition in Stop Mode and Wait Mode

7.7.1   Normal Operating Mode

Normal operating mode is classified into the five modes shown below.
In normal operating mode, the CPU clock and peripheral clock are provided to operate the CPU and peripherals. Power consumption is controlled by the CPU clock frequency. The higher the CPU clock frequency is, the more processing power increases. The lower the CPU clock frequency is, the less power consumption is required. Power consumption can be reduced by stopping oscillators that are not being used.

(1) PLL Mode (high speed mode)

In this mode, the PLL clock is selected as the base clock source, and the main clock is provided as the reference clock source for the PLL frequency synthesizer. High speed mode enables the CPU to operate at the maximum operating frequency. The PLL clock divided by 2 becomes the base clock. The base clock frequency should be identical to that of the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

(2) PLL Mode (medium speed mode)

This mode indicates all modes in PLL mode except high speed mode. The PLL clock divided by 2, 3, 4, or 6 becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

(3) Low Speed Mode

In this mode, a low speed clock is used as the base clock source. The low speed clock becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

(4) Low Power Mode

This is a state where the main clock oscillator and the PLL frequency synthesizer are stopped after switching to low speed mode. The sub clock or the on-chip oscillator clock divided by 4 becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fC32, which is the only peripheral clock available, can be used as the count source for timers A and B. By setting the MRS bit in the VRCR register to 1 (main regulator stopped), this mode consumes even less power than the modes above.

(5) PLL Self-oscillation Mode

In this mode, the PLL clock is selected as the base clock source, and the main clock is not provided as the reference clock source for the PLL frequency synthesizer. The PLL frequency synthesizer self-oscillates at its own frequency. The PLL clock divided by 2, 3, 4, or 6 becomes the base clock and the base clock divided by 1 to 4 becomes the CPU clock. fAD, f1, f8, f32, and f2n can be used as the peripheral clocks. When the sub clock or the on-chip oscillator clock is provided, fC32 can be used as the count source for timers A and B.

The state transition within normal operating mode can be very complicated; therefore only the block diagrams of typical state transitions are shown. Figures 7.18 to 7.20 show block diagrams of the respective state transitions: state when the sub clock is used, state when the main clock divided by 256 is used, and state when the on-chip oscillator clock is used. As for the state transitions other than the above, setting of each register and the usage notes below can be used as references.

- PLL can be switched from PLL oscillating to self-oscillating by setting the SEO bit in the PLC1 register to 1. Set the SEO bit to 1 (self-oscillating) before setting the CM05 bit in the CM0 register to 0 (main clock oscillator disabled) to stop the main clock.
- The divide ratio of the clock should be increased and the frequency should be decreased by using bits BCD1 to BCD0 in the CCR register or bits PM36 to PM35 in the PM3 register before setting the SEO bit to 0 (PLL oscillating) in order to switch back PLL self-oscillation mode to PLL mode. Set back the settings of bits BCD1 to BCD0 and bits PM36 to PM35 once PLL oscillation is stabilized after setting the SEO bit to 0.
- Before switching the CPU clock to another clock, that clock should be stabilized. In particular, the sub clock oscillator may require more time to stabilize [1]. Therefore, certain waiting time to switch should be taken by a program immediately after turning the MCU on or exiting stop mode.

Note:
  1. Contact the oscillator manufacturer for details on oscillator stabilization time.

Figure 7.20   State Transition When Using the On-chip Oscillator Clock

7.7.2   Wait Mode

The base clock stops in wait mode, so clocks generated by the base clock, the CPU clock and peripheral bus clock, stop running as well. Thus the CPU and watchdog timer, operated by these two clocks, also stop. However, the watchdog timer continues operating when the PM22 bit in the PM2 register is 1 (on-chip oscillator selected as count source for the watchdog timer). Since the main clock, sub clock, PLL clock, and on-chip oscillator clock continue running, the peripherals using these clocks also continue operating.

7.7.2.1   Peripheral Clock Source Stop Function

When the CM02 bit in the CM0 register is 1 (peripheral clock source stopped in wait mode), power consumption is reduced since peripheral clocks f1, f8, f32, f2n (when the clock source is the peripheral clock source), and fAD stop running in wait mode. fC32 and f2n (when the clock source is the main clock) do not stop running.

7.7.2.2   Entering Wait Mode

To enter wait mode, the following procedures should be completed before the WAIT instruction is executed.

- Initial setting
    Set the wake-up interrupt priority level (bits RLVL2 to RLVL0 in registers RIPL1 and RIPL2) to 7.
    Then set each interrupt request level.
- Steps before entering wait mode
  (1) Set the I flag to 0.
  (2) Set the interrupt request level for each interrupt source (interrupt number from 1 to 127) to 0, if its interrupt request level is not 0.
  (3) Perform a dummy read of any of the interrupt control registers.
  (4) Set the processor interrupt priority level (IPL) in the flag register to 0.
  (5) Enable interrupts temporarily by executing the following instructions:
      FSET I
      NOP
      NOP
      FCLR I
  (6) Set the interrupt request level for the interrupt to exit wait mode.
      Do not rewrite the interrupt control register after this step.
  (7) Set the IPL in the flag register.
  (8) Set the interrupt priority level for resuming to the same level as the IPL.
      Interrupt request level for the interrupt to exit wait mode > IPL = Interrupt priority level for resuming
  (9) Set the CM20 bit in the CM2 register to 0 (disable oscillator stop detection) when the oscillator stop detection is used.
  (10)Enter either low speed mode or low power mode.
  (11)Set the I flag to 1.
  (12)Execute the WAIT instruction.
- After exiting wait mode
    Set the wake-up interrupt priority level to 7 immediately after exiting wait mode.

7.7.2.3   Pin State in Wait Mode

Table 7.4 lists the pin state in wait mode.

Table 7.4   Pin State in Wait Mode

Pin		State in Wait Mode
Ports		The state immediately before entering wait mode is held
DA0, DA1		The state immediately before entering wait mode is held
CLKOUT	When a low speed clock is selected	The clock is output
	When f8 or f32 is selected	The clock is output when the CM02 bit in the CM0 register is 0 (no peripheral clock source stopped in wait mode). The state immediately before entering wait mode is held when the CM02 bit is 1 (peripheral clock source stopped in wait mode)

7.7.2.4   Exiting Wait Mode

The MCU exits wait mode by a hardware reset, an NMI, or a peripheral interrupt assigned to software interrupt number from 0 to 63.

To exit wait mode using either a hardware reset or NMI, without using peripheral interrupts, set bits ILVL2 to ILVL0 for the peripheral interrupts to 000b (interrupt disabled) before executing the WAIT instruction.

The CM02 bit setting in the CM0 register affects the peripheral interrupts. When the CM02 bit is 0 (peripheral clock source not stopped in wait mode), peripheral interrupts for software interrupt numbers from 0 to 63 can be used to exit wait mode. When this bit is 1 (peripheral clock source stopped in wait mode), peripherals operated using clocks (f1, f8, f32, f2n whose clock source is the peripheral clock source, and fAD) generated by the peripheral clock source stop operating. Therefore, the peripheral interrupts cannot be used to exit wait mode. However, peripherals operated using clocks which are independent from the peripheral clock source (fC32, external clock, and f2n whose clock source is the main clock) do not stop operating. Thus, interrupts generated by these peripherals and assigned to software interrupt numbers from 0 to 63 can be used to exit wait mode.

The CPU clock used when exiting wait mode by a peripheral interrupt or an NMI is the same clock used when the WAIT instruction is executed.

Table 7.5 lists interrupts used to exit wait mode and usage conditions.

Table 7.5   Interrupts for Exiting Wait Mode and Usage Conditions

Interrupt	When the CM02 Bit is 0	When the CM02 Bit is 1
NMI	Available	Available
External interrupt [1]	Available	Available
Key input interrupt	Available	Available
Low voltage detection interrupt	Available	Available
Watchdog timer interrupt	Should not be used	Should not be used
Timer A interrupt Timer B interrupt	Available in any mode	Available in event counter mode, or when the count source is fC32 or f2n (when the main clock is selected as the clock source)
Serial interface interrupt [2]	Available when an internal or external clock is used	Available when the external clock or f2n (when the main clock is selected as the clock source) is used
A/D conversion interrupt	Available in single mode or single-sweep mode	Should not be used
Intelligent I/O interrupt	Available	Should not be used
LIN Low detection interrupt	Available	Available
CAN wake-up interrupt	Available	Available

Notes:
1.   INT6 to INT8 are available in the intelligent I/O interrupt only.
2.   UART3 and UART4 are excluded.

7.7.3   Stop Mode

In stop mode, all of the clocks, except for those that are protected, stop running. That is, the CPU and peripherals, operated by the CPU clock and peripheral clock, also stop. This mode saves the most power.

7.7.3.1   Entering Stop Mode

To enter stop mode, the following procedures should be done before the STOP instruction is executed.

- Initial setting
  Set the wake-up interrupt priority level (bits RLVL2 to RLVL0 in registers RIPL1 and RIPL2) to 7. Then set each interrupt request level.
- Steps before entering stop mode
  (1) Set the I flag to 0.
  (2) Set the interrupt request level for each interrupt source (interrupt number from 1 to 127) to 0, if the interrupt request level is not 0.
  (3) Perform a dummy read of any of the interrupt control registers.
  (4) Set the processor interrupt priority level (IPL) in the flag register to 0.
  (5) Enable interrupts temporarily by executing the following instructions:
    FSET I
    NOP
    NOP
    FCLR I
  (6) Set the interrupt request level for the interrupt to exit stop mode.
    Do not rewrite the interrupt control register after this step.
  (7) Set the IPL in the flag register.
  (8) Set the interrupt priority level for resuming to the same level as the IPL.
    Interrupt request level for the interrupt to exit stop mode > IPL = Interrupt priority level for resuming
  (9) Set the CM20 bit in the CM2 register to 0 (oscillator stop detection disabled) when the oscillator stop detection is used.
  (10)Change the base clock to either the main clock divided by 256 (f256) or the on-chip oscillator clock divided by 4 (fOCO4).
  (11)Set the I flag to 1.
  (12)Execute the STOP instruction.
- After exiting stop mode
  Set the wake-up interrupt priority level to 7 immediately after exiting stop mode.

7.7.3.2   Pin State in Stop Mode

Table 7.6 lists the pin state in stop mode.

Table 7.6   Pin State in Stop Mode

Pin		State in Stop Mode
Ports		The state immediately before entering stop mode is held
DA0, DA1		The state immediately before entering stop mode is held
CLKOUT	When a low speed clock is selected	High
	When f8 or f32 is selected	The state immediately before entering stop mode is held
XIN		High-impedance
XOUT		High
XCIN, XCOUT		High-impedance

7.7.3.3   Exiting Stop Mode

The MCU exits stop mode by a hardware reset, NMI, low voltage detection interrupt, or a peripheral interrupt assigned to software interrupt number from 0 to 63.

To exit stop mode using either a hardware reset or NMI, without using peripheral interrupts, set bits ILVL2 to ILVL0 for the peripheral interrupts to 000b (interrupt disabled) before executing the STOP instruction.

The CPU clock used when exiting stop mode by a peripheral interrupt or NMI is the same clock used when the STOP instruction is executed.

Table 7.7 lists interrupts used to exit stop mode and usage conditions.

Table 7.7   Interrupts for Exiting Stop Mode and Usage Conditions

Interrupt	Usage Condition
NMI	
Low voltage detection interrupt	
External interrupt	INT6 to INT8 are available when intelligent I/O interrupt is used
Key input interrupt	
Timer A interrupt Timer B interrupt	Available when a timer counts an external pulse with a frequency of 100 Hz or less in event counter mode
Serial interface interrupt [1]	Available when an external clock is used
LIN Low detection interrupt	
CAN wake-up interrupt	

Note:
1. UART3 and UART4 are excluded.

7.8   System Clock Protection

The system clock protection disables clock change when the PLL clock is selected as the base clock source. This prevents the CPU clock from stopping due to a runaway program.

When the PM21 bit in the PM2 register is set to 1 (clock change disabled), the following bits cannot be written to:

- Bits CM02 and CM05 in the CM0 register
- The CM10 bit in the CM1 register
- The CM20 bit in the CM2 register
- The PM27 bit in the PM2 register

To use the system clock protection, set the CM05 bit in the CM0 register to 0 (main clock oscillator enabled) and the BCS bit in the CCR register to 0 (PLL clock selected as base clock source) before the following procedure is done:

(1) Set the PRC1 bit in the PRCR register to 1 (write to the PM2 register enabled).
(2) Set the PM21 bit in the PM2 register to 1 (clock change disabled).
(3) Set the PRC1 bit in the PRCR register to 0 (write to the PM2 register disabled).

7.9   Notes on Clock Generator

7.9.1   Sub Clock

7.9.1.1   Oscillator Constant Matching

The constant matching of the sub clock oscillator should be evaluated in both cases when the drive strength is high and low.
Contact the oscillator manufacturer for details on the oscillation circuit constant matching.

7.9.2   Power Control

Do not switch the base clock source until the oscillation of the clock to be used has stabilized. However, this does not apply to the on-chip oscillator since it starts running immediately after the CM31 bit in the CM3 register is set to 1.
To switch the base clock source from the PLL clock to a low speed clock, use the MOV.L or OR.L instruction to set the BCS bit in the CCR register to 1.

- Program example in assembly language
    OR.L   #80h, 0004h

- Program example in C language
    asm("OR.L #80h, 0004h");

7.9.2.1   Stop Mode

- To exit stop mode using a reset, apply a low signal to the $\overline{\text{RESET}}$ pin until the main clock oscillation stabilizes.

7.9.2.2   Suggestions for Power Saving

The following are suggestions to reduce power consumption when programming or designing systems.

- I/O pins:
  If inputs are floating, both transistors may be conducting. Set unassigned pins to input mode and connect each of them to VSS via a resistor, or set them to output mode and leave them open.
- A/D converter:
  When not performing the A/D conversion, set the VCUT bit in the AD0CON1 register to 0 (VREF disconnected). To perform the A/D conversion, set the VCUT bit to 1 (VREF connected) and wait at least 1 µs before starting conversion.
- D/A converter:
  When not performing the D/A conversion, set the DAiE bit in the DACON register (i = 0, 1) to 0 (output disabled) and the DAi register to 00h.
- Peripheral clock stop:
  When entering wait mode, power consumption can be reduced by setting the CM02 bit in the CM0 register to 1 to stop the peripheral clock source. However, this setting does not stop the fC32.

8. Bus

This MCU has a fast bus (CPU bus) and a slow bus (peripheral bus). Figure 8.1 shows a block diagram of the bus.
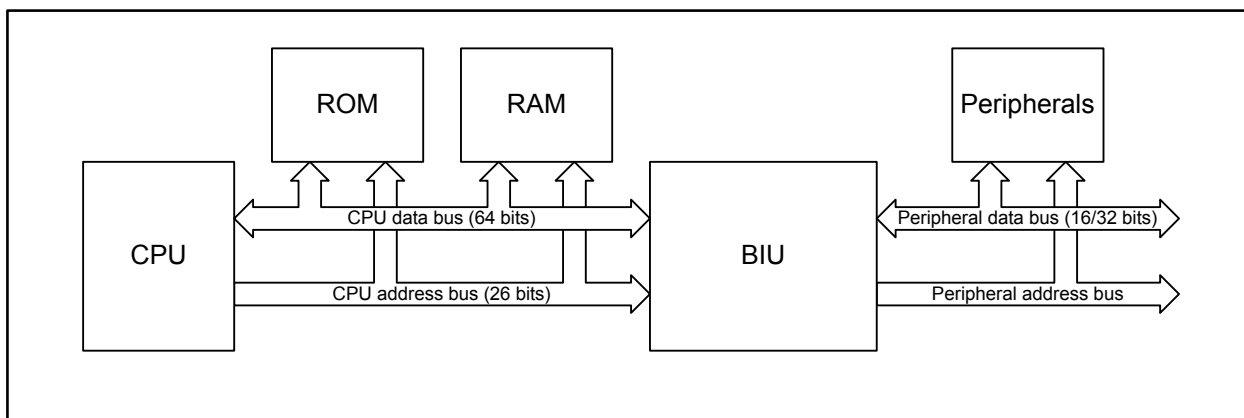

Figure 8.1   Bus Block Diagram

8.1   Bus Setting

The bus setting is controlled by the PBC register.
Table 8.1 lists the bus setting and its source.

Table 8.1   Bus Setting and Source

Bus Setting	Source
Internal SFR bus timing	PBC register

8.2   Peripheral Bus Timing Setting

The 16-/32-bit wide peripheral bus operates at a frequency up to 32 MHz (the theoretical value and the maximum frequency of each product group are as defined by f(BCLK) in 29. "Electrical Characteristics"). The timing adjustment and bus-width conversion with the faster, 64-bit wide CPU bus are controlled in the bus interface unit (BIU).

Figure 8.2 shows the PBC register which determines the peripheral bus timing.

Peripheral Bus Control Register [1, 2]

	Symbol	Address	Reset Value
	PBC	001Fh-001Eh	0504h

Bit Symbol	Bit Name	Function	RW
PRD0	Read Timing Setting Bit	Select from the three options below according to the peripheral bus clock setting (bits PCD1 and PCD0 in the CCR register). When bits PCD1 and PCD0 are set to: 1. 01b : 00100b 2. 10b : 01101b 3. 11b : 01111b	RW
PRD1			
PRD2			
PRD3			
PRD4			
— (b7-b5)	Reserved	Should be written with 0	RW
PWR0	Write Timing Setting Bit	Select from the three options below according to the peripheral bus clock setting (bits PCD1 and PCD0 in the CCR register). When bits PCD1 and PCD0 are set to: 1. 01b : 00101b 2. 10b : 01010b 3. 11b : 01111b	RW
PWR1			
PWR2			
PWR3			
PWR4			
— (b15-b13)	Reserved	Should be written with 0	RW

Notes:
1. Set the PRR register to AAh (write enabled) before rewriting this register.
2. Set this register only once after a reset. Do not rewrite this register after setting the CCR register.

Figure 8.2   PBC Register

9.   Protection

This function protects important registers from being easily overwritten when a program goes out of control. Registers used to protect other registers from being rewritten are as follows: PRCR, PRCR2 to PRCR4, and PRR.

9.1   Protect Register (PRCR Register)

Figure 9.1 shows the PRCR register. Registers protected by bits in the PRCR register are listed in Table 9.1.

Table 9.1   Registers Protected by the PRCR Register

Bit	Protected Registers
PRC0	CM0, CM1, CM2, and PM3
PRC1	PM0, PM2, INVC0, INVC1, and IOBC
PRC2	PLC0, PLC1, PD9, and P9_iS (i = 0 to 7)

The PRC2 bit becomes 0 (write disabled) when a write operation is performed in any other address after this bit is set to 1 (write enabled). Set the PRC2 bit to 1 just before rewriting registers PD9, P9_iS, PLC0, and PLC1 (i = 0 to 7). No interrupt handling or DMA transfers should be inserted between these two instructions. Bits PRC1 and PRC0 do not become 0 even if a write operation is performed in any other address. These bits should be set to 0 by a program.

Protect Register

— (b7-b2)	Reserved	Should be written with 0	RW
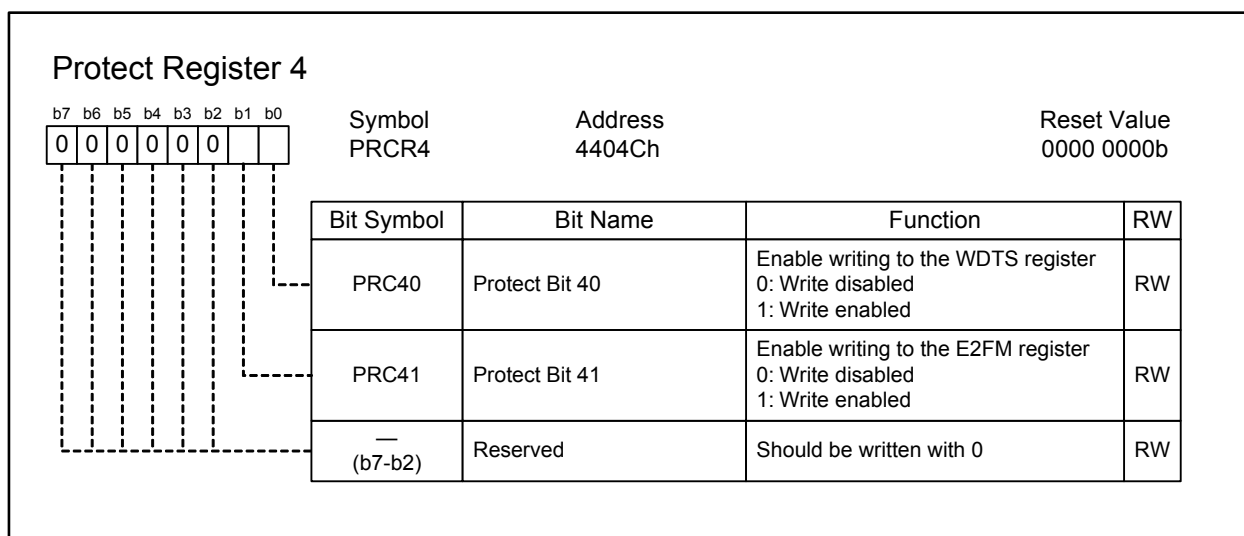

Figure 9.4   PRCR4 Register

9.5   Protect Release Register (PRR Register)

Figure 9.5 shows the PRR register. Registers protected by the PRR register are as follows: CCR, FMCR, PBC, and FEBC.

To write to the registers above, the PRR register should be set to AAh (write enabled). Otherwise, the PRR register should be set to any value other than AAh to protect the above registers from unexpected write accesses.

Figure 9.5   PRR Register

10.Interrupts

10.1   Interrupt Types

Figure 10.1 shows the types of interrupts.

Notes:
1. The peripheral interrupts are generated by the corresponding peripherals in the MCU.
2. This interrupt is used exclusively as a development support tool. Users are not allowed to use this interrupt.
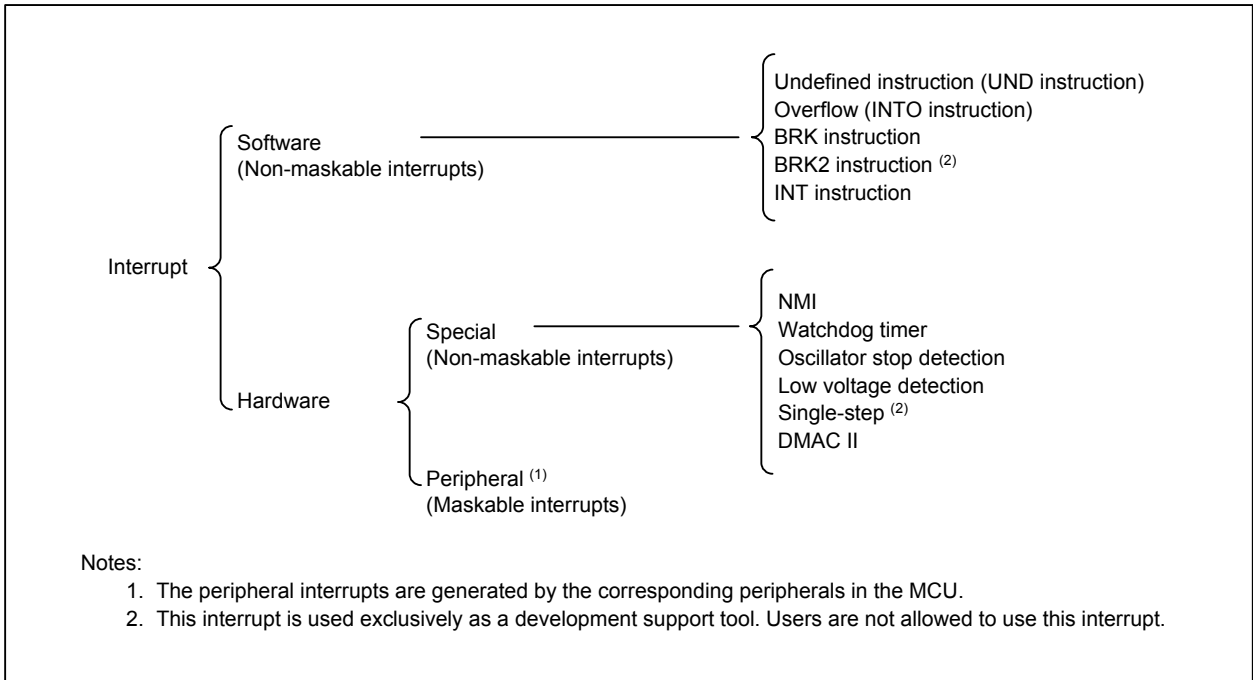

Figure 10.1   Interrupts

Interrupts are also classified into maskable/non-maskable.

(1)   Maskable Interrupts

Maskable interrupts can be disabled by the interrupt enable flag (I flag).
The priority can be configured by assigning an interrupt request level.

(2)   Non-maskable Interrupts

Maskable interrupts cannot be disabled by the interrupt enable flag (I flag).
The interrupt priority cannot be configured.

10.2 Software Interrupts

Software interrupts are non-maskable. A software interrupt occurs by executing an instruction.
There are five types of software interrupts shown below.

(1) Undefined Instruction Interrupt

This interrupt occurs when the UND instruction is executed.

(2) Overflow Interrupt

This interrupt occurs when the INTO instruction is executed while the O flag is 1. The following instructions may change the O flag to 1, depending on the operation result:
ABS, ADC, ADCF, ADD, ADDF, ADSF, CMP, CMPF, CNVIF, DIV, DIVF, DIVU, DIVX, EDIV, EDIVU, EDIVX, MUL, MULF, MULU, MULX, NEG, RMPA, ROUND, SBB, SCMPU, SHA, SUB, SUBF, SUNTIL, and SWHILE

(3) BRK Instruction Interrupt

This interrupt occurs when the BRK instruction is executed.

(4) BRK2 Instruction Interrupt

This interrupt occurs when the BRK2 instruction is executed.
This interrupt is only meant for use as a development support tool and users are not allowed to use it.

(5) INT Instruction Interrupt

This interrupt occurs when the INT instruction is executed with a selected software interrupt number from 0 to 255. Software interrupt numbers 0 to 127 are designated for peripheral interrupts. That is, the INT instruction with a software interrupt number from 0 to 127 has the same interrupt handler as that for peripheral interrupts.
The stack pointer (SP) used for this interrupt differs depending on the software interrupt numbers. For software interrupt numbers 0 to 127, when an interrupt request is accepted, the U flag is saved and set to 0 to select the interrupt stack pointer (ISP) during the interrupt sequence. The saved data of the U flag is restored upon returning from the interrupt handler. For software interrupt numbers 128 to 255, the stack pointer does not change during the interrupt sequence.

10.3   Hardware Interrupts

There are two kinds of hardware interrupts: special interrupts and peripheral interrupts.
In peripheral interrupts, only one interrupt with the highest priority can be specified as a fast interrupt.

10.3.1   Special Interrupts

Special interrupts are non-maskable. There are five special interrupts shown below.

(1)   NMI (Non Maskable Interrupt)

This interrupt occurs when an input signal at the $\overline{\text{NMI}}$ pin switches from high to low. Refer to 10.11 "NMI" for details.

(2)   Watchdog Timer Interrupt

The watchdog timer generates this interrupt. Refer to 11. "Watchdog Timer" for details.

(3)   Oscillator Stop Detection Interrupt

This interrupt occurs when the MCU detects a main clock oscillator stop. Refer to 7.2 "Oscillator Stop Detection" for details.

(4)   Low Voltage Detection Interrupt

This interrupt occurs when a low voltage input to VCC is detected by the voltage detector. Refer to 6.2 "Low Voltage Detector" for details.

(5)   Single-step Interrupt

This interrupt is only meant for use as a development support tool and users are not allowed to use it.

10.3.2   Peripheral Interrupts

Peripheral interrupts occur when an interrupt request from a peripheral in the MCU is accepted. They share the interrupt vector with software interrupt numbers 0 to 127 for the INT instruction. Peripheral interrupts are maskable.
Refer to Tables 10.2 to 10.5 for details on the interrupt sources. Refer to the relevant descriptions for details on each function.

10.4   Fast Interrupt

A fast interrupt enables the CPU to accelerate interrupt response. In peripheral interrupts, only one interrupt with the highest priority can be specified as the fast interrupt.

Use the following procedure to enable a fast interrupt:

(1) Set the both FSIT bit in registers RIPL1 and RIPL2 to 1 (interrupt request level 7 available for fast interrupt).

(2) Set the both DMAII bit in registers RIPL1 and RIPL2 to 0 (interrupt request level 7 available for interrupts).

(3) Set the start address of the fast interrupt handler to the VCT register.

Under the conditions above, bits ILVL2 to ILVL0 in the interrupt control register should be set to 111b (level 7) to enable the fast interrupt. No other interrupts should be set to interrupt request level 7.

When the fast interrupt is accepted, the flag register (FLG) and program counter (PC) are saved to the save flag register (SVF) and save PC register (SVP), respectively. The program is executed from the address indicated by the VCT register.

To return from the fast interrupt handler, the FREIT instruction should be executed. The values saved into registers SVF and SVP are restored to the FLG register and PC, respectively.

10.5   Interrupt Vectors

Each interrupt vector has a 4-byte memory space, in which the start address of the associated interrupt handler is stored. When an interrupt request is accepted, a jump to the address set in the interrupt vector takes place. Figure 10.2 shows an interrupt vector.

	MSB	LSB
Vector address + 0	Lower byte of an address	
Vector address + 1	Mid-lower byte of an address	
Vector address + 2	Mid-upper byte of an address	
Vector address + 3	Upper byte of an address	
Figure 10.2   Interrupt Vector

10.5.1 Fixed Vector Table

The fixed vector table is allocated in addresses FFFFFFDCh to FFFFFFFFh. Table 10.1 lists the fixed vector table.

Table 10.1 Fixed Vector Table

Interrupt Source	Vector Addresses (Address (L) to Address (H))	Remarks	Reference
Undefined instruction	FFFFFFDCh to FFFFFFDFh	Interrupt by the UND instruction	R32C/100 Series Software Manual
Overflow	FFFFFFE0h to FFFFFFE3h	Interrupt by the INTO instruction	
BRK instruction	FFFFFFE4h to FFFFFFE7h	If address FFFFFFE7h is FFh, a jump to the interrupt vector of software interrupt number 0 in the relocatable vector table takes place	
—	FFFFFFE8h to FFFFFFEBh	Reserved	
—	FFFFFFECh to FFFFFFEFh	Reserved	
Watchdog timer Oscillator stop detection Low voltage detection	FFFFFFF0h to FFFFFFF3h	These addresses are shared by the watchdog timer interrupt, oscillator stop detection interrupt, and low voltage detection interrupt	11. "Watchdog Timer" 7. "Clock Generator" 6.2 "Low Voltage Detector"
—	FFFFFFF4h to FFFFFFF7h	Reserved	
NMI	FFFFFFF8h to FFFFFFFBh	External interrupt by the $\overline{\text{NMI}}$ pin	
Reset	FFFFFFFCh to FFFFFFFFh		5. "Resets"

10.5.2 Relocatable Vector Table

The relocatable vector table occupies a 1024-byte memory space from the start address set in the INTB register. Tables 10.2 to 10.5 list the relocatable vector table entries.
An address in a multiple of 4 should be set in the INTB register for a faster interrupt sequence.

Table 10.2   Relocatable Vector Table (1/4)

Interrupt Source	Vector Table Relative Addresses (Address (L) to Address (H)) [1]	Software Interrupt Number	Reference
BRK instruction [2]	+0 to +3 (0000h to 0003h)	0	R32C/100 Series Software Manual

Notes:
1. Each entry is relative to the base address in the INTB register.
2. Interrupts from this source cannot be disabled by the I flag.
3. In I2C mode, interrupts are generated by NACK, ACK, or detection of a START condition/STOP condition.

Table 10.3   Relocatable Vector Table (2/4)

Notes:
  1. Entries in this table cannot be used to exit wait mode or stop mode.
  2. Each entry is relative to the base address in the INTB register.
  3. Interrupts from this source cannot be disabled by the I flag.

10.6   Interrupt Request Acceptance

Software interrupts and special interrupts are accepted whenever their interrupt request is generated. Peripheral interrupts, however, are only accepted if the conditions below are met:

- I flag is 1
- IR bit is 1
- Bits ILVL2 to ILVL0 > IPL

The I flag, IPL, IR bit, and bits ILVL2 to ILVL0 do not affect each other. The I flag and IPL are in the FLG register. The IR bit and bits ILVL2 to ILVL0 are in the interrupt control register.

The following section describes these flag and bits.

10.6.1   I Flag and IPL

The I flag (interrupt enable flag) enables or disables maskable interrupts. When the I flag is set to 1 (enabled), all maskable interrupts are enabled; when it is set to 0 (disabled), they are disabled. The I flag becomes 0 after a reset.

The IPL (processor interrupt priority level) consists of 3 bits and indicates eight interrupt priority levels from 0 to 7. An interrupt becomes acceptable when its interrupt request level is higher than the specified IPL (bits ILVL2 to ILVL0 > IPL).

Table 10.6 lists interrupt request levels classified by the IPL.

Table 10.6   Acceptable Interrupt Request Levels and IPL

IPL			Acceptable Interrupt Request Levels
IPL2	IPL1	IPL0	
1	1	1	All maskable interrupts are disabled
1	1	0	Level 7 only
1	0	1	Level 6 and above
1	0	0	Level 5 and above
0	1	1	Level 4 and above
0	1	0	Level 3 and above
0	0	1	Level 2 and above
0	0	0	Level 1 and above

10.6.2   Interrupt Control Registers

Each peripheral interrupt is controlled by an interrupt control register.
Figures 10.3 and 10.4 show the interrupt control registers.

Interrupt Control Register

b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value

IR	Interrupt Request Flag	0: No interrupt requested 1: Interrupt requested [1]	RW
— (b7-b4)	No registers bits; should be written with 0 and read as undefined value		—

Note:
  1. This bit can only be set to 0 (do not set it to 1).

Figure 10.3   Interrupt Control Register (1/2)

Interrupt Control Register

b7 b6 b5 b4 b3 b2 b1 b0

Symbol	Address	Reset Value
INT0IC to INT2IC	009Eh, 007Eh, 009Ch	XX00 X000b
INT3IC to INT5IC	007Ch, 009Ah, 007Ah	XX00 X000b
INT6IC to INT8IC	00FEh, 00DEh, 00FCh	XX00 X000b

Bit Symbol	Bit Name	Function	RW
ILVL0	Interrupt Request Level Select Bit	b2 b1 b0 0 0 0 : Level 0 (interrupt disabled) 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	RW
ILVL1			RW
ILVL2			RW
IR	Interrupt Request Flag	0: No interrupt requested 1: Interrupt requested [1]	RW
POL	Polarity Select Bit	0: Select the falling edge or a low 1: Select the rising edge or a high [2]	RW
LVS	Level/Edge Sensitive Select Bit	0: Edge sensitive 1: Level sensitive [3]	RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Notes:
1. This bit can only be set to 0 (do not set it to 1).
2. Set this bit to 0 (the falling edge) to set the corresponding bit in registers IFSR0 and IFSR1 to 1 (both edges).
3. Set the corresponding bit in registers IFSR0 and IFSR1 to 0 (one edge) to select the level sensitive.

Figure 10.4   Interrupt Control Register (2/2)

Bits ILVL2 to ILVL0
The interrupt request level is selected by setting bits ILVL2 to ILVL0. The higher the level is, the higher interrupt priority is.
When an interrupt request is generated, its request level is compared to the IPL. The interrupt is accepted only when the interrupt request level is higher than the IPL. When bits ILVL2 to ILVL0 are set to 000b, the interrupt is disabled.

IR bit
The IR bit becomes 1 (interrupt requested) when an interrupt request is generated; this bit setting is retained until the interrupt request is accepted. When the request is accepted and a jump to the corresponding interrupt vector takes place, the IR bit becomes 0 (no interrupt requested).
The IR bit can be set to 0 by a program. This bit should not be set to 1.

When rewriting the interrupt control register, no corresponding interrupt request should be generated. If there is a possibility that an interrupt request may be generated, disable the interrupt request before rewriting the register.

When enabling an interrupt immediately after changing the interrupt control register, insert NOPs between two instructions or perform a dummy read of the interrupt control register so that the interrupt enable flag (I flag) cannot become 1 (interrupt enabled) before writing to the interrupt control register is completed.

If an interrupt request is generated for the register being rewritten, the IR bit may not become 1 depending on the instruction being used. If it matters, use one of the following instructions to rewrite the register:

- AND
- OR
- BCLR
- BSET

If the AND or BCLR instruction is used to set the IR bit to 0, the IR bit may not become 0 as these instructions cause the interrupt request to be retained during the rewrite. To prevent this from happening, rewrite the register using the MOV instruction. To set just the IR bit to 0, first temporarily store the read value to memory or a CPU internal register, then execute either the AND or BCLR instruction in the stored area. After that, write the value back to the register using the MOV instruction.

10.6.3 Wake-up IPL Setting Register

Set the wake-up IPL setting registers (registers RIPL1 and RIPL2) when using an interrupt to exit wait or stop mode, or using the fast interrupt.
Refer to 7.7.2 "Wait Mode", 7.7.3 "Stop Mode", or 10.4 "Fast Interrupt" for details.
Figure 10.5 shows registers RIPL1 and RIPL2.

Wake-up IPL Setting Register i (i = 1, 2) [1]

	Symbol	Address	Reset Value
b7 b6 b5 b4 b3 b2 b1 b0	RIPL1, RIPL2	4407Fh, 4407Dh	XX0X 0000b

Bit Symbol	Bit Name	Function	RW
RLVL0	Interrupt Priority Level for Wake-up Select Bit [2]	b2 b1 b0 0 0 0 : Level 0 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	RW
RLVL1			RW
RLVL2			RW
FSIT	Fast Interrupt Select Bit [3]	0: Use interrupt request level 7 for normal interrupt 1: Use interrupt request level 7 for fast interrupt [4]	RW
— (b4)	No register bit; should be written with 0 and read as undefined value		—
DMAII	DMA II Select Bit [5]	0: Use interrupt request level 7 for interrupt 1: Use interrupt request level 7 for DMA II transfer [4]	RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Notes:
1. Registers RIPL1 and RIPL2 should be set with the same values.
2. The MCU exits wait mode or stop mode when the request level of the requested interrupt is higher than the level selected using bits RLVL2 to RLVL0. Set these bits to the same value as the IPL in the FLG register.
3. When the FSIT bit is 1, an interrupt with interrupt request level 7 becomes the fast interrupt. In this case, set the interrupt request level to level 7 with only one interrupt.
4. Set either the FSIT or DMAII bit to 1. The fast interrupt and DMAC II cannot be used simultaneously.
5. Set bits ILVL2 to ILVL0 in the interrupt control register after the DMAII bit is set. DMA II transfer is not affected by the I flag or IPL.

Figure 10.5   Registers RIPL1 and RIPL2

10.6.4   Interrupt Sequence

An interrupt sequence is performed from when an interrupt request has been accepted until the interrupt handler starts.

When an interrupt request is generated while an instruction is being executed, the requested interrupt is evaluated in the priority resolver after the current instruction is completed, and the interrupt sequence starts from the next cycle.

However, for instructions RMPA, SCMPU, SIN, SMOVB, SMOVF, SMOVU, SOUT, SSTR, SUNTIL, and SWHILE, when an interrupt request is generated while an instruction is being executed, the current instruction is suspended, and the interrupt sequence starts.

The interrupt sequence is as follows:

(1) The CPU acknowledges the interrupt request to obtain the interrupt information (the interrupt number, and the interrupt request level) from the interrupt controller. Then the corresponding IR bit becomes 0 (no interrupt requested).

(2) The FLG register value before the interrupt sequence is stored to a temporary register in the CPU. The temporary register is inaccessible to users.

(3) The following bits in the FLG register become 0:
  • The I flag (interrupt enable flag): interrupt disabled
  • The D flag (debug flag): single-step interrupt disabled
  • The U flag (stack pointer select flag): ISP selected

(4) The temporary register value in the CPU is saved to the stack, or to the SVF register in case of the fast interrupt.

(5) The PC value is saved to the stack, or to the SVP register in case of the fast interrupt.

(6) The interrupt request level for the accepted interrupt is set in the IPL (processor interrupt priority level).

(7) The corresponding interrupt vector is read from the interrupt vector table.

(8) This interrupt vector is stored into the PC.

After the interrupt sequence is completed, an instruction is executed from the start address of the interrupt handler.

10.6.5   Interrupt Response Time

The interrupt response time, as shown in Figure 10.6, consists of two non-overlapping time segments: (a) the period from when an interrupt request is generated until the instruction being executed is completed; and (b) the period required for the interrupt sequence.
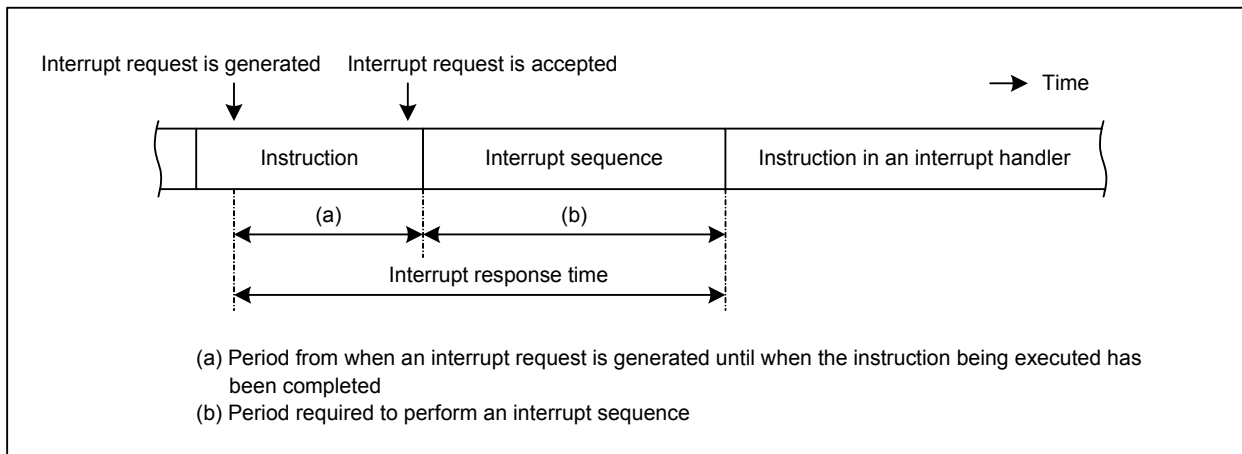

Figure 10.6   Interrupt Response Time

Period (a) varies depending on the instruction being executed. Instructions, such as LDCTX and STCTX in which registers are sequentially saved into or restored from the stack, require the longest time. For example, the STCTX instruction requires at least 30 cycles for 10 registers to be saved. It requires more time if the WAIT instruction is in the stack.
Period (b) is listed in Table 10.7.

Table 10.7   Interrupt Sequence Execution Time [1]

Interrupt	Execution Time in Terms of CPU Clock
Peripherals	$13 + \alpha$ cycles [2]
INT instruction	11 cycles
NMI	10 cycles
Watchdog timer Oscillator stop detection Low voltage detection	11 cycles
Undefined instruction	12 cycles
Overflow	12 cycles
BRK instruction (relocatable vector table)	16 cycles
BRK instruction (fixed vector table)	19 cycles
BRK2 instruction	19 cycles
Fast interrupt	11 cycles

Notes:
1. These are the values when the interrupt vectors are aligned to the addresses in multiples of 4 in the internal ROM. However, the condition does not apply to the fast interrupt.
2. α is the number of waits to access SFRs minus 2.

10.6.6   IPL after Accepting an Interrupt Request

When a peripheral interrupt request is accepted, the interrupt request level is set in the IPL (processor interrupt priority level).

Software interrupts and special interrupts have no interrupt request level. When these interrupt requests are accepted, the value listed in Table 10.8 is set in the IPL as the interrupt request level.

Table 10.8   Interrupts without Interrupt Request Level and IPL

Interrupt Sources without Interrupt Request Level	IPL Value to be Set
NMI, watchdog timer, oscillator stop detection, low voltage detection	7
Reset	0
Software	Unchanged

10.6.7   Register Saving

In the interrupt sequence, the FLG register and PC values are saved to the stack, in that order. Figure 10.7 shows the stack status before and after an interrupt request is accepted.

In the fast interrupt sequence, the FLG register and PC values are saved to registers SVF and SVP, respectively.

If there are any other registers to be saved to the stack, save them at the beginning of the interrupt handler. A single PUSHM instruction saves all registers except the frame base register (FB) and stack pointer (SP).
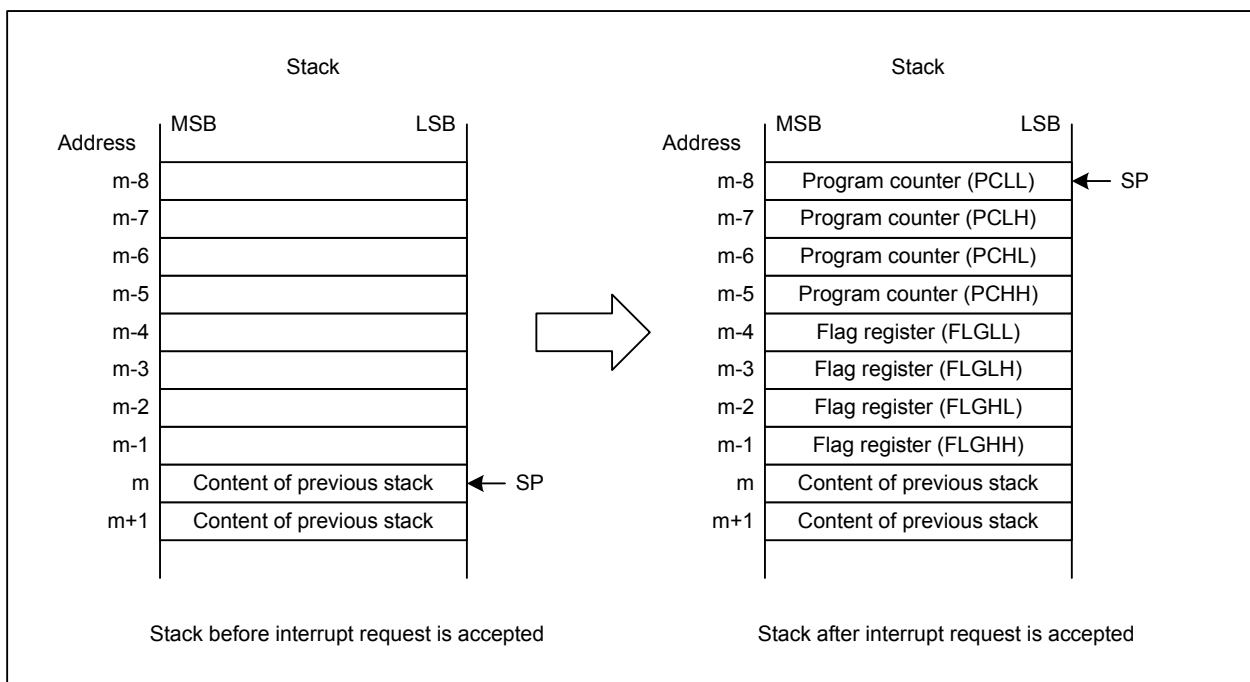

Figure 10.7   Stack Before and After an Interrupt Request is Accepted

10.7 Register Restoring from Interrupt Handler

When the REIT instruction is executed at the end of the interrupt handler, the FLG register and PC values, which are saved in the stack, are restored, and the program resumes the operation that was interrupted. In the fast interrupt, execute the FREIT instruction to restore them from the save registers, instead.

To restore the register values which are saved by software in the interrupt handler, use an instruction such as POPM before the REIT or FREIT instruction.

If the register bank is switched in the interrupt handler, the bank is automatically switched back to the original register bank by the REIT or FREIT instruction.

10.8 Interrupt Priority

If two or more interrupt requests are detected at an interrupt request sampling point, the interrupt request with higher priority is accepted.

For maskable interrupts (peripheral interrupts), the interrupt request level select bits (bits ILVL2 to ILVL0) select a request level. If two or more interrupt requests have the same request level, the interrupt with higher priority, predetermined by hardware, is accepted.

The priorities of the reset and special interrupts, such as the watchdog timer interrupt, are determined by the hardware. Note that the reset has the highest priority. The following is the priority order determined by the hardware:

$$\text{Reset} > \begin{matrix} \text{Watchdog timer} \\ \text{Oscillator stop detection} \\ \text{Low voltage detection} \end{matrix} > \text{NMI} > \text{Peripherals}$$

Software interrupts are not governed by priority. A jump to the interrupt handler takes place whenever the relevant instruction is executed.

10.9 Priority Resolver

The priority resolver selects an interrupt that has the highest priority among requested interrupts detected at the same sampling point.

Figure 10.8 shows the priority resolver.
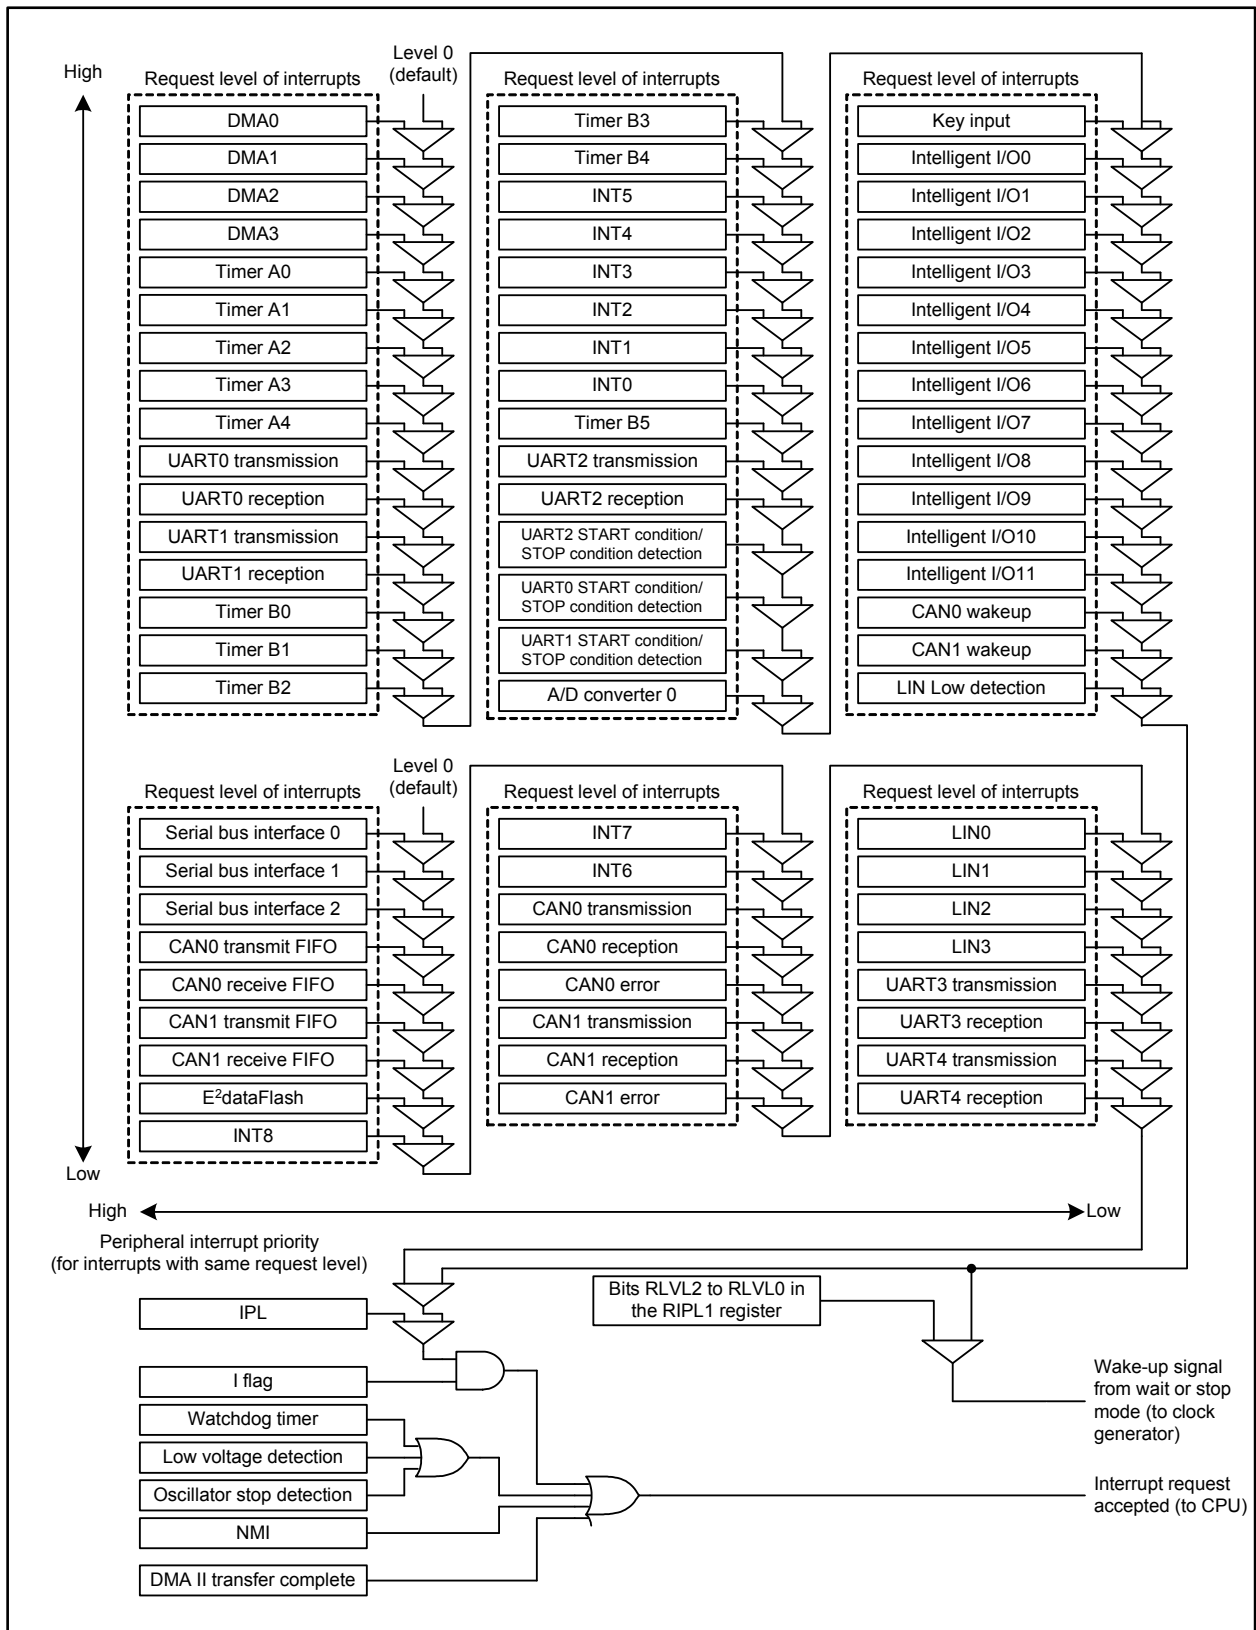

Figure 10.8 Priority Resolver

10.10 External Interrupt

An external interrupt occurs by an external input applied to the $\overline{\text{INT}i}$ pin (i = 0 to 8). Set the LVS bit in the INTiIC register to select whether an interrupt is triggered by the effective edge(s) (edge sensitive), or by the effective level (level sensitive) of the input signal. The polarity of the input signal is selected by setting the POL bit in the same register.

When using edge-triggered interrupts, setting the IFSR0j bit in the IFSR0 register to 1 (both edges) causes interrupt requests to be generated on both rising and falling edges of the external input applied to the $\overline{\text{INT}j}$ pin (j = 0 to 5). This also applies to setting the IFSR1n bit (n = m - 6) in the IFSR1 register to 1 (both edges) for the $\overline{\text{INT}m}$ pin (m = 6 to 8). Set the POL bit in the corresponding register to 0 (falling edge) to set the IFSR0j bit or the IFSR1n bit to 1.

When using level-triggered interrupts, set the IFSR0j or IFSR1n bit to 0 (one edge). When an effective level, which is selected by the POL bit, is detected on the $\overline{\text{INT}i}$ pin, the IR bit in the INTiIC register becomes 1. The IR bit does not become 0 even if the signal level at the $\overline{\text{INT}i}$ pin changes. This bit is set to 0 when the INTi interrupt is accepted or it is set to 0 by a program.

Figures 10.9 and 10.10 show registers IFSR0 and IFSR1, respectively.

External Interrupt Request Source Select Register 0

Figure 10.10 IFSR1 Register

The external interrupt signal has a digital filtering function for noise reduction. This function enables the interrupt controller to sample input signals with a selected clock and to pass pulses only which match the level three times sequentially.
Figures 10.11 to 10.13 show registers INTF0 to INTF2.

Figure 10.14 INTSR Register

10.11 NMI

The NMI (non maskable interrupt) occurs when an input signal at the $\overline{NMI}$ pin switches from high to low. This non maskable interrupt is disabled after a reset. To enable this interrupt, set the PM24 bit in the PM2 register to 1 after setting the interrupt stack pointer (ISP) at the beginning of the program. The $\overline{NMI}$ pin shares a pin with port P8_5, which enables the P8_5 bit in the P8 register to indicate the input level at the $\overline{NMI}$ pin.

Note:

1. When not using the NMI, do not change the reset value of the PM24 bit in the PM2 register.

10.12 Key Input Interrupt

The key input interrupt is enabled by setting ports P10_4 to P10_7 as input ports.

The interrupt request is generated if any of the signals applied to ports P10_4 to P10_7 switch from high to low. This interrupt also functions as key wake-up to exit wait or stop mode. Figure 10.15 shows a block diagram of the key input interrupt. If any of the ports are held low, signals applied to other ports are not detected as interrupt request signals.

To use the key input interrupt, every register from P10_4S to P10_7S should be set to 00h (I/O port) and bits PD10_4 to PD10_7 should be set to 0 (input). This is the only setting available for the key input interrupt.
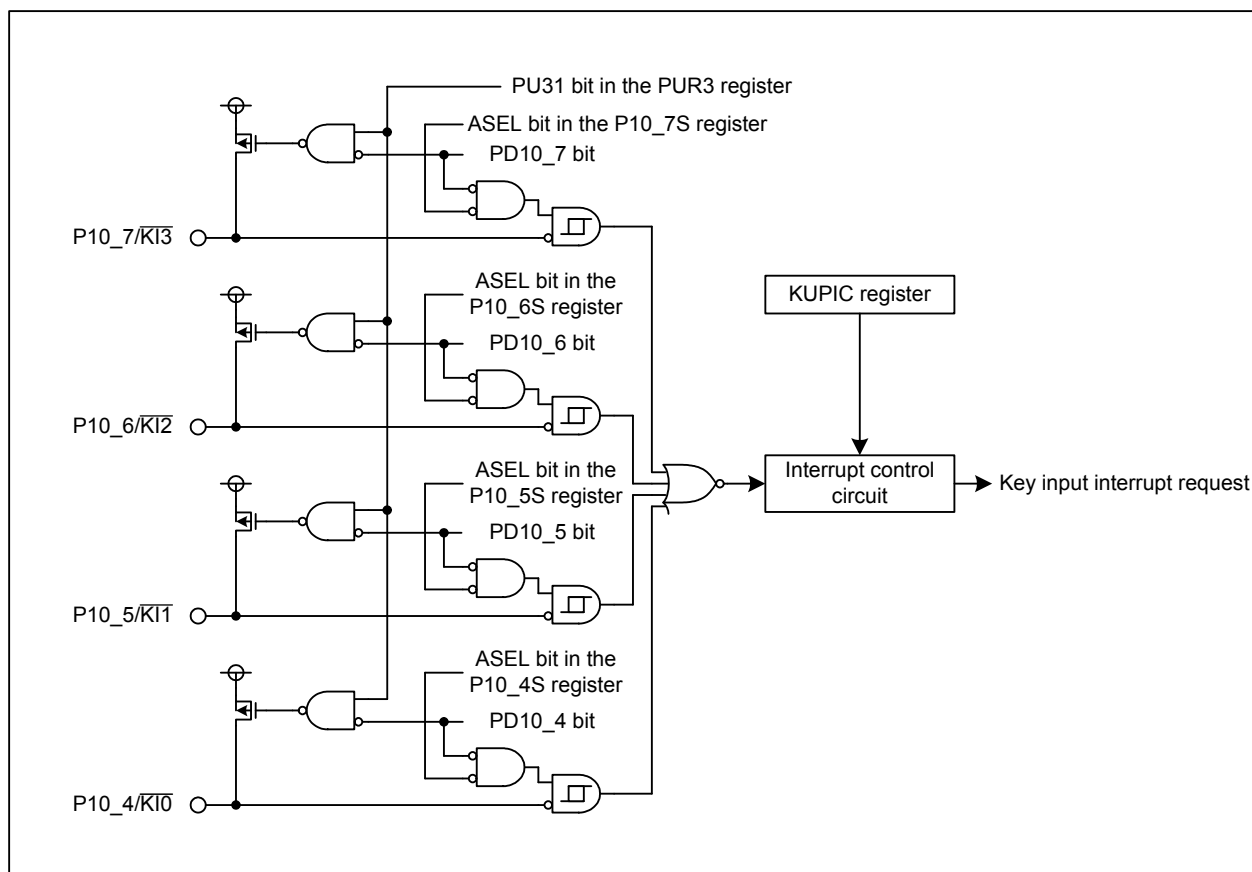

Figure 10.15 Key Input Interrupt Block Diagram

10.13 Intelligent I/O Interrupt

The intelligent I/O interrupt is assigned to software interrupt numbers 44 to 55.

Figure 10.16 shows a block diagram of the intelligent I/O interrupt. Figures 10.17 and 10.18 show registers IIOiIR and IIOiIE, respectively (i = 0 to 11).

To use the intelligent I/O interrupt, set the IRLT bit in the IIOiIE register to 1 (interrupt requests used for interrupt).

The intelligent I/O interrupt has multiple request sources. When an interrupt request is generated with an intelligent I/O function, the corresponding bit in the IIOiIR register becomes 1 (interrupt requested). If the corresponding bit in the IIOiIE register is 1 (interrupt enabled), the IR bit in the corresponding IIOiIC register changes to 1 (interrupt requested).

After the IR bit setting changes from 0 to 1, it remains unchanged if a bit in the IIOiIR register becomes 1 by another interrupt request source and the corresponding bit in the IIOiIE register is 1.

Bits in the IIOiIR register do not become 0 even if an interrupt is accepted. They should be set to 0 by either the AND or BCLR instruction. Note that every generated interrupt request is ignored until these bits are set to 0.

To use the intelligent I/O interrupt as a DMAC II trigger, set the IRLT bit in the IIOiIE register to 0 (interrupt requests used for DMA or DMA II) and the bit used for the interrupt source to 1 (interrupt enabled) in the IIOiIE register.

Figure 10.18 Registers IIO0IE to IIO11IE

10.14   Notes on Interrupts

10.14.1   ISP Setting

The interrupt stack pointer (ISP) is initialized to 00000000h after a reset. Set a value to the ISP before an interrupt is accepted, otherwise the program may go out of control. A multiple of 4 should be set to the ISP, which enables faster interrupt sequence due to less memory access.

When using NMI, in particular, since this interrupt cannot be disabled, set the PM24 bit in the PM2 register to 1 (NMI enabled) after setting the ISP at the beginning of the program.

10.14.2   NMI

- NMI cannot be disabled once the PM24 bit in the PM2 register is set to 1 (NMI enabled). This bit setting should be done only when using NMI.

- When the PM24 bit in the PM2 register is 1 (NMI enabled), the P8_5 bit in the P8 register is enabled just for monitoring the $\overline{\text{NMI}}$ pin state. It is not enabled as a general port.

10.14.3   External Interrupts

- The input signal to the $\overline{\text{INTi}}$ pin requires the pulse width specified in the electrical characteristics (i = 0 to 8). If the pulse width is narrower than the specification, an external interrupt may not be accepted.

- When the effective level or edge of the $\overline{\text{INTi}}$ pin (i = 0 to 8) is changed by the following bits: bits POL, LVS in the INTiIC register, the IFSR0i bit (i = 0 to 5) in the IFSR0 register, and the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register, the corresponding IR bit may become 1 (interrupt requested). When setting the above mentioned bits, preset bits ILVL2 to ILVL0 in the INTiIC register to 000b (interrupt disabled). After setting the above mentioned bits, set the corresponding IR bit to 0 (no interrupt requested), then rewrite bits ILVL2 to ILVL0.

- The interrupt input signals to pins $\overline{\text{INT6}}$ to $\overline{\text{INT8}}$ are also connected to bits INT6R to INT8R in registers IIO9IR to IIO11IR. Therefore, these input signals, when assigned to the intelligent I/O, can be used as a source for exiting wait mode or stop mode. Note that these signals are enabled only on the falling edge and not affected by the following bit settings: bits POL and LVS in the INTiIC register (i = 0 to 8), IFSR0i bit (i = 0 to 5) in the IFSR0 register, and the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register.

11. Watchdog Timer

The watchdog timer is used to detect program runaway. The 15-bit watchdog counter decrements with the cycle which is the peripheral bus clock frequency or on-chip oscillator clock frequency divided by the prescaler.

Select either an interrupt request or a reset with the CM06 bit in the CM0 register for when the watchdog timer underflows. Once the CM06 bit is set to 1 (reset), it cannot be changed to 0 (watchdog timer interrupt) by a program. It can be set to 0 only by a reset.

The watchdog timer has two prescalers. One is the on-chip oscillator clock divided by 1, 2, 4 or 8; the other is the peripheral bus clock divided by 16 or 128. To select the divide ratio for the former, set bits WDK3 and WDK2 in the WDK register. To select the divide ratio for the latter, set the WDC7 bit in the WDC register.

The count source for the watchdog timer is set by the PM22 bit in the PM2 register. When the peripheral bus clock is selected as the count source, the watchdog timer is stopped in wait mode, stop mode, or when the $\overline{\text{HOLD}}$ signal is driven low. It resumes counting from the value held when exiting the mode or state. When the on-chip oscillator clock is selected, the watchdog timer does not stop.

The general formula to calculate a watchdog timer period is:

$$\text{Watchdog timer period} = \frac{\text{Prescaler divisor (16 or 128)} \times 32768}{\text{Peripheral bus clock frequency}}$$

or

$$\text{Watchdog timer period} = \frac{\text{Prescaler divisor (1, 2, 4, or 8)} \times 2048}{\text{On-chip oscillator clock frequency}}$$

For example, when the peripheral bus clock is selected as the count source and it is 1/2 of 64 MHz CPU clock and the prescaler has a divide-by-16 operation, the watchdog timer period is approximately 16.4 ms. Depending on the timing of when a value is written to the WDTS register, a marginal error of one prescaler output cycle (maximum) may occur in the watchdog timer period.

The watchdog timer is initialized when a write operation to the WDTS register is performed or when a watchdog timer interrupt request is generated. The prescaler is initialized only when the MCU is reset.

After a reset, the watchdog timer starts counting automatically if the OFS area of the flash memory are preset. When the WDTON bit in the OFS area is 1, both the watchdog timer and the prescaler are stopped. They start counting when a write operation to the WDTS register is performed. When the WDTON bit is 0, both the watchdog timer and the prescaler automatically start counting after a reset.

Figure 11.1 shows a block diagram of the watchdog timer. Figures 11.2 to 11.5 show registers associated with the watchdog timer.

Figure 11.1   Watchdog Timer Block Diagram

Watchdog Timer Control Register

CSPM	Post-reset Count Source Protect Mode Select Bit [2, 3]	After a reset, count source protect mode is 0: Enabled (PM22 = 1) 1: Disabled (PM22 = 0)	[1]

Notes:
1. Rewrite this area by the flash programmer. It cannot be rewritten by a program.
2. To enable the count source protect mode, set bits WDTON and CSPM to 0. Once the watchdog timer starts, the PM22 bit in the PM2 register cannot be rewritten.
3. These bit settings are disabled when the WDTON bit is 1. The values set to these bits are reflected to registers WDK and PM2 when the WDTON bit is 0.

Figure 11.5   OFS Area

12. DMAC

Direct memory access (DMA) is a system that can control data transfer without using a CPU instruction.
The R32C/100 Series' four channel DMA controller (DMAC) transmits 8-bit (byte), 16-bit (word), or 32-bit (long word) data in cycle-steal mode from a source address to a destination address each time a transfer request is generated.

The DMAC, which shares a data bus with the CPU, has a higher bus access priority than the CPU. This allows the DMAC to perform fast data transfer when a transfer request is generated.

Figure 12.1 shows a map of the CPU-internal registers associated with DMAC. Table 12.1 lists DMAC specifications. Figures 12.2 to 12.10 show registers associated with DMAC. Since the registers shown in Figure 12.1 are allocated in the CPU, the LDC or STC instruction should be used to write to the registers.

DMAC-associated Registers

Register	Description

Maximum transfer bytes		64-Mbytes (when 32-bit data is transferred), 32-Mbytes (when 16-bit data is transferred), 16-Mbytes (when 8-bit data is transferred)
DMA request sources [1]		Falling edge or both edges of signals applied to pins INT0 to INT3 or pins $\overline{INT6}$ to $\overline{INT8}$ Interrupt requests from timers A0 to A4 Interrupt requests from timers B0 to B5 Transmit/receive interrupt requests from UART0 to UART4 A/D conversion interrupt requests Intelligent I/O interrupt requests Serial bus interface interrupt requests Software trigger
Channel priority		DMA0 > DMA1 > DMA2 > DMA3 (DMA0 has the highest priority)
Transfer sizes		8 bits, 16 bits, or 32 bits
Addressing modes		Incrementing addressing or non-incrementing addressing
Transfer modes	Single transfer	Transfer is completed when the DCTi register becomes 00000000h
	Repeat transfer	When the DCTi register becomes 00000000h, the value of the DCRi register is reloaded into the DCTi register to continue the DMA transfer
DMA transfer complete interrupt request generation timing		When the DCTi register changes from 00000001h to 00000000h
DMA transfer start-up	Single transfer	When a DMA transfer request is generated after the DCTi register is set to a value other than 00000000h and bits MDi1 and MDi0 in the DMDi register are set to 01b (single transfer)
	Repeat transfer	When a DMA transfer request is generated after the DCTi register is set to a value other than 00000000h and bits MDi1 and MDi0 are set to 11b (repeat transfer)
DMA transfer stop	Single transfer	When bits MDi1 and MDi0 are set to 00b (DMA transfer disabled)
	Repeat transfer	When bits MDi1 and MDi0 are set to 00b (DMA transfer disabled)
Reload timing to DCTi, DSAi, or DDAi register		When the DCTi register changes from 00000001h to 00000000h in repeat transfer mode
Minimum DMA transfer cycles		3

Note:
1.   DMA transfer does not affect any interrupts.

The DMA transfer request is available by two different sources: software and hardware. More concretely, they are a write access to the DSR bit in the DMiSL2 register and an interrupt request output from a function specified in bits DSEL4 to DSEL0 in the DMiSL register, and in bits DSEL24 to DSEL20 in the DMiSL2 register (i = 0 to 3). Unlike interrupt requests, the DMA transfer request is not affected by the I flag or the interrupt control register. Therefore this request can be accepted even when interrupts are disabled. Since the DMA transfer does not affect any interrupts, either, the IR bit in the interrupt control register is not changed by the DMA transfer.

Figure 12.10 Registers DDR0 to DDR3

12.1   Transfer Cycle

The transfer cycle is composed of bus cycles to read data from (source read) or to write data to (destination write) memory or an SFR.

The read and write bus cycles vary with the setting of registers DSAi and DDAi, the width and timing of the data bus connected to the relevant device (i = 0 to 3).

12.1.1   Effect of Transfer Address and Data Bus Width

Table 12.4 lists the incremental bus cycles caused by transfer address alignment or data bus width.

Table 12.4   Incremental Bus Cycles Caused by Transfer Address and Data Bus Width

Transfer Data Unit	Data Bus Width	Transfer Address	Bus Cycles to be Incremented	Bus Cycles Generated
8-bit transfer	8 to 64 bits	n	0	[n]
16-bit transfer	8 bits	n	+1	[n] - [n + 1]
	16 bits	2n	0	[2n]
		2n + 1	+1	[2n + 1] - [2n + 2]
	32 bits	4n	0	[4n]
		4n + 1	0	[4n + 1]
		4n + 2	0	[4n + 2]
		4n + 3	+1	[4n + 3] - [4n + 4]
	64 bits	8n	0	[8n]
		8n + 1	0	[8n + 1]
		8n + 2	0	[8n + 2]
		8n + 3	0	[8n + 3]
		8n + 4	0	[8n + 4]
		8n + 5	0	[8n + 5]
		8n + 6	0	[8n + 6]
		8n + 7	+1	[8n + 7] - [8n + 8]
32-bit transfer	8 bits	n	+3	[n] - [n + 1] - [n + 2] - [n + 3]
	16 bits	4n	+1	[4n] - [4n + 2]
		4n + 1	+2	[4n + 1] - [4n + 2] - [4n + 4]
		4n + 2	+1	[4n + 2] - [4n + 4]
		4n + 3	+2	[4n + 3] - [4n + 4] - [4n + 6]
	32 bits	4n	0	[4n]
		4n + 1	+1	[4n + 1] - [4n + 4]
		4n + 2	+1	[4n + 2] - [4n + 4]
		4n + 3	+1	[4n + 3] - [4n + 4]
	64 bits	8n	0	[8n]
		8n + 1	0	[8n + 1]
		8n + 2	0	[8n + 2]
		8n + 3	0	[8n + 3]
		8n + 4	0	[8n + 4]
		8n + 5	+1	[8n + 5] - [8n + 8]
		8n + 6	+1	[8n + 6] - [8n + 8]
		8n + 7	+1	[8n + 7] - [8n + 8]

12.1.2   Effect of Bus Timing

In the R32C/100 Series, a separate bus is connected to each device. The bus width and bus timing vary with each device. Table 12.5 lists the bus width and access cycles for each device.

Table 12.5   Bus Width and Bus Cycles

Device	Addresses [1]	Bus Width	Access Cycles [2]	Reference Clock
Flash memory	FFE00000h to FFFFFFFFh	64-bit	2 or 3 [3]	CPU clock
Data flash	00060000h to 00061FFFh	64-bit	5	CPU clock
RAM	00000400h to 0003FFFFh	64-bit	1 or 2 [4]	CPU clock
SFR space	00000000h to 0000001Fh	16-bit	3 [5]	Peripheral bus clock
	00000020h to 000003FFh	16-bit	2 [5]	Peripheral bus clock
SFR2 space	00040000h to 00041FFFh	16-bit	2 [5]	Peripheral bus clock
	00042000h to 00043FFFh	32-bit	2 [5]	Peripheral bus clock
	00044000h to 000440DFh	16-bit	2 [5, 6]	Peripheral bus clock
	000440E0h to 000443FFh	16-bit	3 [5, 6]	Peripheral bus clock
	00044400h to 00045FFFh	16-bit	2 [5, 6]	Peripheral bus clock
	00046000h to 000467FFh	32-bit	3 [5, 6]	Peripheral bus clock
	00046800h to 00047FFFh	32-bit	2 [5, 6]	Peripheral bus clock
	00048000h to 0004FFFFh	64-bit	2	CPU clock

Notes:
1. Reserved spaces are included.
2. Access cycles are based on each bus clock.
3. An access to the same page as the previous time requires two cycles. Otherwise, three cycles are required.
4. If write cycles are generated sequentially, each write cycle except the initial one has two access cycles. A read cycle just after a write cycle has also two access cycles.
5. If SFRs are sequentially accessed, each access except the initial one has one additional base clock cycle.
6. Up to one access cycle may be added depending on the phase of peripheral bus clock.

Figure 12.11 shows an example of source-read bus cycles in a transfer cycle. In this figure, the number of source-read bus cycles is shown under different conditions, provided that the destination address is in an internal RAM with one bus cycle of destination-write. In a real operation, the transfer cycles change according to conditions for destination-write bus cycles as well as for source-read bus cycles. To calculate a transfer cycle, respective conditions should be applied to both destination-write bus cycle and source-read bus cycle. In (B) of Figure 12.11, for example, if two bus cycles are generated, bus cycles required for the destination-write is two as well as for the source-read.

(A) One bus cycle of source-read is generated
    Example: 16-bit data transfer from address 8n in the RAM

CPU clock

CPU address bus   CPU in operation   DSA   DDA   CPU in operation

CPU data bus   CPU in operation   [DSA] [DDA]   CPU in operation

CPU $\overline{RD}$ signal

CPU $\overline{WR}$ signal

(B) Two bus cycles of source-read are generated
    Example: 16-bit data transfer from address 8n+7 in the RAM

CPU clock

CPU address bus   CPU in operation   DSA   DSA+1   DDA   CPU in operation

CPU data bus   CPU in operation   [DSA] [DSA+1] [DDA]   CPU in operation

CPU $\overline{RD}$ signal

CPU $\overline{WR}$ signal

(C) One bus cycle of source-read is generated with one wait cycle
    Example: 16-bit data transfer from address 16n in the ROM

CPU clock

CPU address bus   CPU in operation   DSA   DDA   CPU in operation

CPU data bus   CPU in operation   [DSA] [DDA]   CPU in operation

CPU $\overline{RD}$ signal

CPU $\overline{WR}$ signal

(D) Two bus cycles of source-read is generated with one wait cycle
    Example: 16-bit data transfer from address 16n+7 in the ROM

CPU clock

CPU address bus   CPU in operation   DSA   DSA+1   DDA   CPU in operation

CPU data bus   CPU in operation   [DSA]   [DSA+1] [DDA]   CPU in operation

CPU $\overline{RD}$ signal

CPU $\overline{WR}$ signal

Note:
1. The above assumes that destination-write completes in one bus cycle. In actual use, the number of
    destination-write bus cycles should be considered according to the conditions such as above.

Figure 12.11   Source-read Bus Cycles in a Transfer Cycle

12.2   DMA Transfer Cycle

The DMA transfer cycles are calculated as follows:

Number of transfer cycles = Source-read bus cycles × j + Destination-write bus cycles × k + 1

where:

j = access cycles for read

k = access cycles for write (refer to Table 12.5)

Each bus cycle, source-read and destination-write, requires at least one cycle. In addition, more cycles may be required depending on the transfer address. Refer to Table 12.4 for details on the required bus cycles.

"+1" in the formula above means a cycle required to decrement the value of DCTi register (i = 0 to 3).

The following are calculation examples:

To transfer 32-bit data from address 400h in the RAM to address 800h in the RAM,

$$Number\ of\ the\ transfer\ cycles\ =\ 1 \times 1 + 1 \times 1 + 1$$
$$=\ 3$$

Thus, there are three cycles.

To transfer 16-bit data from the AD00 register at address 380h to registers P1 and P0 at addresses 3C1h and 3C0h, respectively, when the peripheral bus clock frequency is half the CPU clock,

$$Number\ of\ the\ transfer\ cycles\ =\ 1 \times 2 \times 2 + 1 \times 2 \times 2 + 1$$
$$=\ 9$$

Thus, there are nine cycles.

12.3   Channel Priority and DMA Transfer Timing

When multiple DMA transfer requests are generated in the same sampling period, between the falling edge of the CPU clock and the next falling edge, these requests are simultaneously input into the DMAC. Channel priority in this case is: DMA0 > DMA1 > DMA2 > DMA3.

Figure 12.12 shows an example of the DMA transfer by external source, specifically when DMA0 and DMA1 requests are simultaneously generated. The DMA0, whose request priority is higher than that of DMA1, is received first to start the transfer and then hands over the bus to the CPU after completing one DMA0 transfer. Once the CPU completes one bus access, the DMA1 transfer starts. The CPU takes the bus back from the DMA1 after one DMA1 transfer is completed.

DMA transfer requests cannot be counted. Only a single transfer is performed even when an $\overline{\text{INTi}}$ interrupt occurs more than once before the bus is granted, as shown by DMA1 in Figure 12.12.
Figure 12.12 DMA Transfer by External Source

12.4   Notes on DMAC

12.4.1   DMAC-associated Register Settings

- Set DMAC-associated registers while bits MDi1 and MDi0 in the DMDi register are 00b (DMA transfer disabled) (i = 0 to 3). Then, set bits MDi1 and MDi0 to 01b (single transfer) or 11b (repeat transfer) at the end of the setup procedure. This procedure also applies when rewriting bits UDAi, USAi, and BWi1 and BWi0 in the DMDi register.

- When rewriting the DMAC-associated registers while DMA transfer is enabled, stop the peripherals that can be DMA triggers so that no DMA transfer request is generated, then set bits MDi1 and MDi0 in the DMDi register of the corresponding channel to 00b (DMA transfer disabled).

- Once a DMA transfer request is accepted, DMA transfer cannot be disabled even if setting bits MDi1 and MDi0 in the DMDi register to 00b (DMA transfer disabled). Do not change the settings of any DMAC-associated registers other than bits MDi1 and MDi0 until the DMA transfer is completed.

- After setting registers DMiSL and DMiSL2, wait at least six peripheral bus clocks to set bits MDi1 and MDi0 in the DMDi register to 01b (single transfer) or 11b (repeat transfer).

12.4.2   Reading DMAC-associated Registers

- Use the following read order to sequentially read registers DMiSL and DMiSL2:
  DM0SL, DM1SL, DM2SL, and DM3SL
  DM0SL2, DM1SL2, DM2SL2, and DM3SL2

13. DMAC II

DMAC II starts by an interrupt request from any peripheral and performs data transfer without a CPU instruction. Transfer sources are selectable from memory, immediate data, memory + memory, and immediate data + memory.
Table 13.1 lists specifications of DMAC II.

Table 13.1   DMAC II Specifications

Item	Specification
DMAC II request sources	Interrupt requests from the peripherals of which bits ILVL2 to ILVL0 in the corresponding interrupt control register are set to 111b (level 7)
Transfer types	• Data in memory is transferred to memory (memory-to-memory transfer) • Immediate data is transferred to memory (immediate data transfer) • Data in memory + data in memory are transferred to memory (calculation result transfer) • Immediate data + data in memory are transferred to memory (calculation result transfer)
Transfer sizes	8 bits or 16 bits
Transfer memory spaces	From a given address in a 64-Mbyte space (00000000h to 01FFFFFFh and FE000000h to FFFFFFFFh) to another given address in the same space [1]
Addressing modes	Individually selectable for each source address and destination address from the following two modes: • Non-incrementing addressing: Address is held constant throughout a data transfer/DMA II transaction • Incrementing addressing: Address increments by 1 (when 8-bit data is transferred) or 2 (when 16-bit data is transferred) after each data transfer
Transfer modes	• Single transfer: Only one data transfer is performed by one transfer request • Burst transfer: Data transfers are continuously performed for the number of times set in the transfer counter by one transfer request • Multiple transfer: Multiple memory-to-memory transfers are performed from different source addresses to different destination addresses by one transfer request
Chain transfer	Data transfer is sequentially performed by switching among multiple DMAC II indexes (transfer information)
DMA II transfer complete interrupt request	An interrupt request is generated when the transfer counter reaches 0000h

Note:
1. When the transfer size is 16 bits and the destination address is FFFFFFFFh, data is transferred to FFFFFFFFh and 00000000h. This also applies when the source address is FFFFFFFFh.

13.1   DMAC II Settings

To use DMAC II, set the following:
- Registers RIPL1 and RIPL2
- DMAC II index
- Interrupt control registers of the peripherals that trigger DMAC II
- Relocatable vectors of the peripherals that trigger DMAC II
- The IRLT bit in the IIOiIE register when using the intelligent I/O interrupt (i = 0 to 11). Refer to 10. "Interrupts" for details on the IIOiIE register.

13.1.1 Registers RIPL1 and RIPL2

When the DMAII bit in registers RIPL1 and RIPL2 is set to 1 (DMA II transfer selected) and the FSIT bit is set to 0 (normal interrupt selected), DMAC II starts by an interrupt request from any peripheral whose bits ILVL2 to ILVL0 in the corresponding interrupt control register are set to 111b (level 7).

Figure 13.1 shows registers RIPL1 and RIPL2.

Wake-up IPL Setting Register i (i = 1, 2) [1]

	Symbol	Address	Reset Value
b7 b6 b5 b4 b3 b2 b1 b0	RIPL1, RIPL2	4407Fh, 4407Dh	XX0X 0000b

Bit Symbol	Bit Name	Function	RW
RLVL0	Interrupt Priority Level for Wake-up Select Bit [2]	b2 b1 b0 0 0 0 : Level 0 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	RW
RLVL1			RW
RLVL2			RW
FSIT	Fast Interrupt Select Bit [3]	0: Use interrupt request level 7 for normal interrupt 1: Use interrupt request level 7 for fast interrupt [4]	RW
— (b4)	No register bit; should be written with 0 and read as undefined value		—
DMAII	DMA II Select Bit [5]	0: Use interrupt request level 7 for interrupt 1: Use interrupt request level 7 for DMA II transfer [4]	RW
— (b7-b6)	No register bits; should be written with 0 and read as undefined value		—

Notes:
1. Registers RIPL1 and RIPL2 should be set with the same values.
2. The MCU exits wait mode or stop mode when the request level of the requested interrupt is higher than the level selected using bits RLVL2 to RLVL0. Set these bits to the same value as the IPL in the FLG register.
3. When the FSIT bit is 1, an interrupt with interrupt request level 7 becomes the fast interrupt. In this case, set the interrupt request level to level 7 with only one interrupt.
4. Set either the FSIT or DMAII bit to 1. The fast interrupt and DMAC II cannot be used simultaneously.
5. Set bits ILVL2 to ILVL0 in the interrupt control register after the DMAII bit is set. DMA II transfer is not affected by the I flag or IPL.

Figure 13.1 Registers RIPL1 and RIPL2

13.1.2   DMAC II Index

The DMAC II index is a data table of 12 to 60 bytes. It stores parameters for transfer mode, transfer counter, source address (or immediate data), operation address as an address to be calculated, destination address, chain transfer base address, and jump address for the DMA II transfer complete interrupt handler.

This DMAC II index should be allocated on the RAM.

Figure 13.2 shows a configuration of the DMAC II index and Table 13.2 lists a configuration example of the DMAC II index.
Figure 13.2   DMAC II Index

The following are the details on the DMAC II index. These parameters should be aligned in the order listed in Table 13.2 according to the transfer mode to be used.

- Transfer mode (MOD)
  Set a transfer mode in 2 bytes. Refer to Figure 13.3 for details on the setting of MOD.
- Transfer counter (COUNT)
  Set a number of transfers in 2 bytes.
- Source address (SADR)
  Set a source address or immediate data in 4 bytes. Note that the two upper bytes of immediate data are ignored.
- Operation address (OADR)
  Set an address in a to-be calculated memory in 4 bytes. This data setting is required only for the calculation transfer.
- Destination address (DADR)
  Set a destination address in 4 bytes.
- Chain transfer base address (CADR)
  Set the start address of the DMAC II index for the next transfer (BASE) in 4 bytes. This data setting is required only for the chain transfer.
- Jump address for the DMA II transfer complete interrupt handler (IADR)
  Set the start address for the DMA II transfer complete interrupt handler in 4 bytes. This data setting is required only for the DMA II transfer complete interrupt.

The symbols above are hereinafter used in place of their respective parameters.

Table 13.2   DMAC II Index Configuration

Transfer Data	Memory-to-memory Transfer/ Immediate Data Transfer				Calculation Transfer				Multiple Transfer
Chain transfer	Not used	Used	Not used	Used	Not used	Used	Not used	Used	Not available
DMA II transfer complete interrupt	Not used	Not used	Used	Used	Not used	Not used	Used	Used	Not available

Figure 13.3 MOD

13.1.3   Interrupt Control Register of the Peripherals

Set bits ILVL2 to ILVL0 in the interrupt control register for the peripheral interrupt triggering DMAC II to 111b (level 7).

13.1.4   Relocatable Vector Table of the Peripherals

Set the start address of the DMAC II index in the interrupt vector space for the peripheral interrupt triggering DMAC II.
To use the chain transfer, allocate the relocatable vector table on the RAM.

13.1.5   IRLT Bit in the IIOiIE Register (i = 0 to 11)

To use the intelligent I/O interrupt as a trigger for DMAC II, set the IRLT bit in the corresponding IIOiIE register to 0 (interrupt request for DMA or DMA II used).

13.2   DMAC II Operation

Set the DMAII bit in registers RIPL1 and RIPL2 to 1 (interrupt request level 7 used for DMA II transfer) to perform a DMA II transfer. DMAC II starts by an interrupt request from any peripheral whose bits ILVL2 to ILVL0 in the corresponding interrupt control register are set to 111b (level 7). These peripheral interrupt requests are available only for DMA II transfer and cannot be used for the CPU.
When an interrupt request is generated with interrupt request level 7, DMAC II starts irrespective of the state of the I flag or IPL.
When a peripheral interrupt request triggering DMAC II and a higher-priority request such as the watchdog timer interrupt, low voltage detection interrupt, oscillator stop detection interrupt, or NMI are simultaneously generated, the higher-priority interrupt is accepted prior to the DMA II transfer, and the DMA II transfer starts after the higher-priority interrupt sequence.

13.3   Transfer Types

DMAC II transfers three types of 8-bit or 16-bit data as follows:
   • Memory-to-memory transfer: Data is transferred from a given memory location in a 64-Mbyte space (addresses 00000000h to 01FFFFFFh and FE000000h to FFFFFFFFh) to another given memory location in the same space.
   • Immediate data transfer: Immediate data is transferred to a given memory location in a 64-Mbyte space.
   • Calculation transfer: Two data are added together and the result is transferred to a given memory location in a 64-Kbyte space.
When 16-bit data is transferred to DADR at FFFFFFFFh, it is transferred to 00000000h as well as FFFFFFFFh. The same transfer is performed when SADR is FFFFFFFFh.

13.3.1   Memory-to-memory Transfer

Data transfer between any two memory locations can be:
   • A transfer from a fixed address to another fixed address
   • A transfer from a fixed address to an address range in memory
   • A transfer from an address range in memory to a fixed address
   • A transfer from an address range in memory to another address range in memory

When increment addressing mode is selected, SADR and DADR increment by 1 in an 8-bit transfer and by 2 in a 16-bit transfer after a data transfer for the next transfer. When SADR or DADR exceeds FFFFFFFFh by the incrementation, it returns to 00000000h. Likewise, when SADR or DADR exceeds 01FFFFFFh, it becomes 02000000h, but an actual transfer is performed for FE000000h.

13.3.2   Immediate Data Transfer

DMAC II transfers immediate data to a given memory location. Either incrementing or non-incrementing addressing mode can be selected for the destination address. Store the immediate data to be transferred into SADR. To transfer 8-bit immediate data, set the data to the lower 1 byte of SADR. The upper 3 bytes are ignored. To transfer 16-bit immediate data, set the data to the lower 2 bytes. The upper 2 bytes are ignored.

13.3.3   Calculation Result Transfer

After two memory data or immediate data and memory data are added together, DMAC II transfers the calculated result to a given memory location. Set an address to be calculated or immediate data to SADR and set the other address to be calculated to OADR. Either incrementing or non-incrementing addressing mode can be selected for source and destination addresses when performing data in memory + data in memory calculation transfer. If the source addressing is in incrementing mode, the operation addressing is also in incrementing mode. When performing immediate data + data in memory calculation transfer, the addressing mode is selectable only for the destination address.

13.4   Transfer Modes

DMAC II provides three types of basic transfer mode: single transfer, burst transfer, and multiple transfer. COUNT determines the number of transfers to be performed. Transfers are not performed when COUNT is 0000h.

13.4.1   Single Transfer

Set the BRST bit in the MOD to 0.
A single data transfer is performed by one transfer request.
When incrementing addressing mode is selected for the source and/or destination address, the address or addresses increment after a data transfer for the next transfer.
COUNT is decremented each time a data transfer is performed. When COUNT reaches 0000h, the DMA II transfer complete interrupt request is generated if the INTE bit in the MOD is 1 (DMA II transfer complete interrupt used).

13.4.2   Burst Transfer

Set the BRST bit in the MOD to 1.
DMAC II continuously transfers data for the number of times determined by COUNT with one transfer request. COUNT decrements each time a data transfer is performed. When COUNT reaches 0000h, the burst transfer is completed. The DMA II transfer complete interrupt request is generated if the INTE bit is 1 (DMA II transfer complete interrupt used).
No interrupts are accepted during a burst transfer.

13.4.3   Multiple Transfer

Set the MULT bit in the MOD to 1.
Multiple memory-to-memory transfers are performed from different source addresses to different destination addresses using one transfer request.
Set bits CNT2 to CNT0 in the MOD to select the number of transfers to be performed from 001b (once) to 111b (seven times). Do not set these bits to 000b.
Allocate the required number of SDARs and DADRs alternately following MOD and COUNT.
When the multiple transfer is selected, the following transfer functions are not available: calculation result transfer, burst transfer, chain transfer, and DMA II transfer complete interrupt.

13.5   Chain Transfer

The chain transfer is available when the CHAIN bit in the MOD is 1.

The chain transfer is performed as follows:

   (1) When a transfer request is generated, a data transfer is performed according to the DMAC II index specified by the corresponding interrupt vector. Either a single transfer (the BRST bit in the MOD is 0) or burst transfer (the BRST bit is 1) is performed according to the BRST bit setting.

   (2) When COUNT reaches 0000h, the value in the interrupt vector in (1) above is overwritten with the value in CADR. Simultaneously, the DMA II transfer complete interrupt request is generated when the INTE bit in the MOD is 1.

   (3) When the next DMA II transfer request is generated, the data transfer is performed according to the DMAC II index specified by the peripheral interrupt vector in (2) above.

Figure 13.4 shows the relocatable vector and DMAC II index in a chain transfer.

To use the chain transfer, the relocatable vector table should be allocated on the RAM.
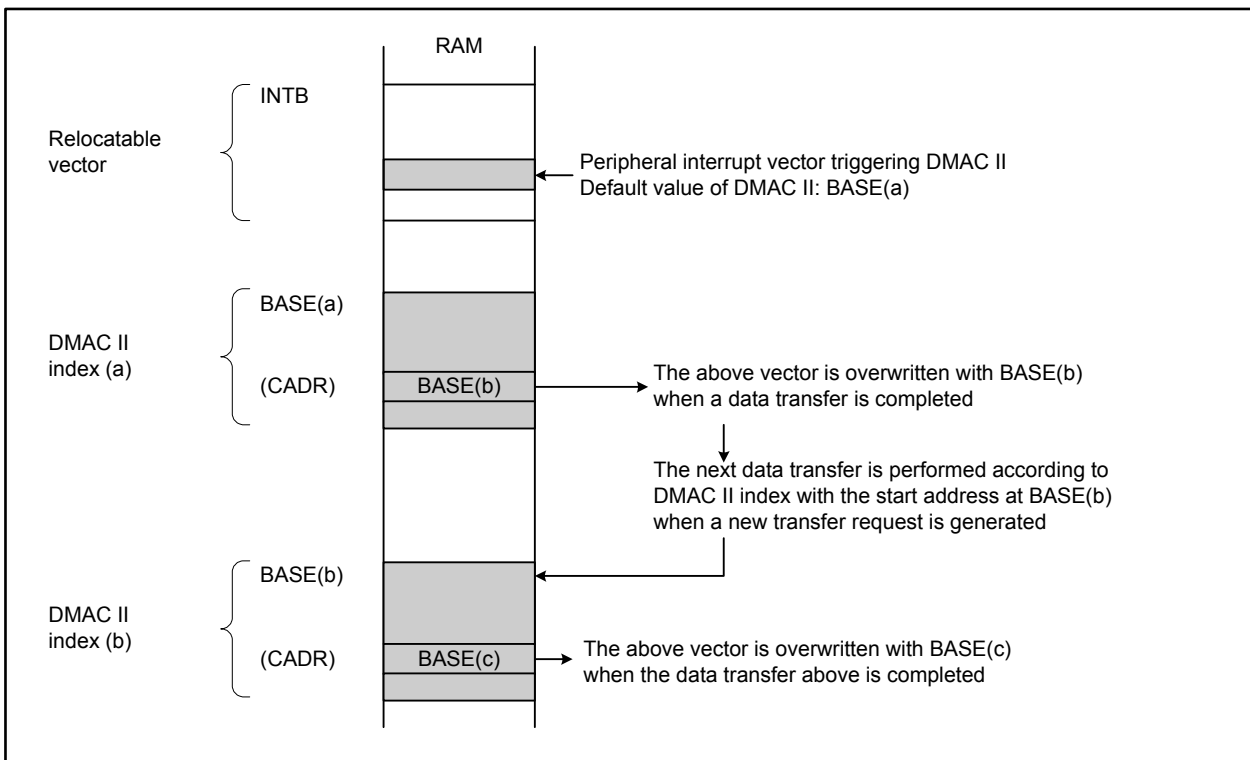

Figure 13.4   Relocatable Vector and DMAC II Index in a Chain Transfer

13.6   DMA II Transfer Complete Interrupt

The DMA II transfer complete interrupt is available when the INTE bit in the MOD is 1.

Set the start address of the DMA II transfer complete interrupt handler to IADR. The interrupt request is generated when COUNT reaches 0000h.

The initial instruction of the interrupt handler is executed in the eighth cycle after a DMA II transfer is completed.

13.7 Execution Time

The DMAC II execution cycle is calculated by the following equations:

Mode other than multiple transfer: $t = 6 + (26 + a + b + c + d) \times m + (4 + e) \times n$ cycles
When using multiple transfer: $t = 21 + (11 + b + c) \times k$ cycles

a: When IMM is 0 (transfer source is immediate data), a is 0;
When IMM is 1 (transfer source is memory), a is -1

b: When UPDS is 1 (source addressing is incrementing), b is 0;
When UPDS is 0 (source addressing is non-incrementing), b is 1

c: When UPDD is 1 (destination addressing is incrementing), c is 0;
When UPDD is 0 (destination addressing is non-incrementing), c is 1

d: When OPER is 0 (calculation transfer is not selected), d is 0;
When OPER is 1 (calculation transfer is selected) and UPDS is 0 (source addressing is immediate data or non-incrementing), d is 7;
When OPER is 1 (calculation transfer is selected) and UPDS is 1 (source addressing is incrementing), d is 8

e: When CHAIN is 0 (chain transfer is not selected), e is 0;
When CHAIN is 1 (chain transfer is selected), e is 4

m: When BRST is 0 (single transfer), m is 1;
When BRST is 1 (burst transfer), m is COUNT

n: When COUNT is 0001h, n is 0; if COUNT is 0002h or more, n is 1

k: The number of transfers set using bits CNT2 to CNT0

The equations above are estimations. The number of cycles may vary depending on CPU state, bus wait state, and DMAC II index allocation.

The figure below applies under the following conditions:
memory-to-memory transfer; incrementing source address; non-incrementing destination address; number of transfers = 2; single transfer mode; using a transfer complete interrupt (transfer counter = 2); no chain transfer

(a = -1, b = 0, c = 1, d = 0, e = 0, m = 1)

First DMA II transfer $t = 6 + (26 - 1 + 0 + 1 + 0) \times 1 + (4 + 0) \times 1 = 36$ cycles
Second DMA II transfer $t = 6 + (26 - 1 + 0 + 1 + 0) \times 1 + (4 + 0) \times 0 = 32$ cycles

Figure 13.5   Transfer Cycles

14. Programmable I/O Ports

There are 120 programmable I/O ports designated from P0 to P15 (excluding P8_5, and P14_0 to P14_2).
Each port status, input or output, can be selected using the direction register except P8_5 and P14_1 which
are input only. The P8_5 bit in the P8 register indicates an $\overline{\text{NMI}}$ input level since the P8_5 shares a pin with
the $\overline{\text{NMI}}$.
Figure 14.1 shows a configuration of programmable I/O ports, and Figures 14.2 and 14.3 show a
configuration of each input-only port.

Note:
    1.   Refer to 26. "I/O Pins" for details on the area enclosed with the dotted line above.
Figure 14.1   Programmable I/O Port Configuration
Figure 14.2   Input-only Port Configuration (1/2)
Figure 14.3   Input-only Port Configuration (2/2)

14.1   Port Pi Register (Pi register, i = 0 to 15)

A write/read operation to the Pi register is required to communicate with external devices. This register consists of a port latch to hold output data and a circuit to read pin states. Bits in the Pi register correspond to respective ports.

When a programmable I/O port is selected in the output function select registers, the value in the port latch is read for output and the pin state is read for input.

Figure 14.4 shows the Pi register.

Port Pi Register (i = 0 to 15)

b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value
	P0 to P3	03C0h, 03C1h, 03C4h, 03C5h	Undefined
	P4 to P7	03C8h, 03C9h, 03CCh, 03CDh	Undefined
	P8 [1], P9, P10	03D0h, 03D1h, 03D4h	Undefined
	P11 [2], P12, P13	03D5h, 03D8h, 03D9h	Undefined
	P14 [1, 2, 3], P15	03DCh, 03DDh	Undefined

Bit Symbol	Bit Name	Function	RW
Pi_0	Port Pi_0 Bit [3]	When the direction bit is 0 (input) A value is written to the corresponding bit. It is not output due to input mode selected. The read value is the corresponding pin state as follows: 0: Low 1: High When the direction bit is 1 (output) A value is written to the corresponding bit as follows: 0: Output low 1: Output high The read value has the same output level as that written to the corresponding bit	RW
Pi_1	Port Pi_1 Bit [1]		RW
Pi_2	Port Pi_2 Bit [3]		RW
Pi_3	Port Pi_3 Bit		RW
Pi_4	Port Pi_4 Bit		RW
Pi_5	Port Pi_5 Bit [1, 2]		RW
Pi_6	Port Pi_6 Bit [2]		RW
Pi_7	Port Pi_7 Bit [2]		RW

Notes:
1. The P8_5 bit in the P8 register and the P14_1 bit in the P14 register are read only.
2. No register bits are assigned to bits P11_5 to P11_7 in the P11 register and the P14_7 bit in the P14 register. These bits should be written with 0 and read as undefined values.
3. Bits P14_0 and P14_2 in the P14 register are reserved. These bits should be written with 0 and read as undefined values.

Figure 14.4   Registers P0 to P15

15. Timers

This MCU has eleven 16-bit timers which are divided into two groups according to their functions: five timer As and six timer Bs. Each timer functions individually. The count source of each timer provides the clock for timer operations such as counting and reloading.

Figures 15.1 and 15.2 show the configuration of timers A and B, respectively.

TCK1 and TCK0, TMOD1 and TMOD0: Bits in the TAiMR register
TAiTGH and TAiTGL: Bits in the ONSF or TRGSR register (i = 0 to 4)
Figure 15.1   Timer A Configuration
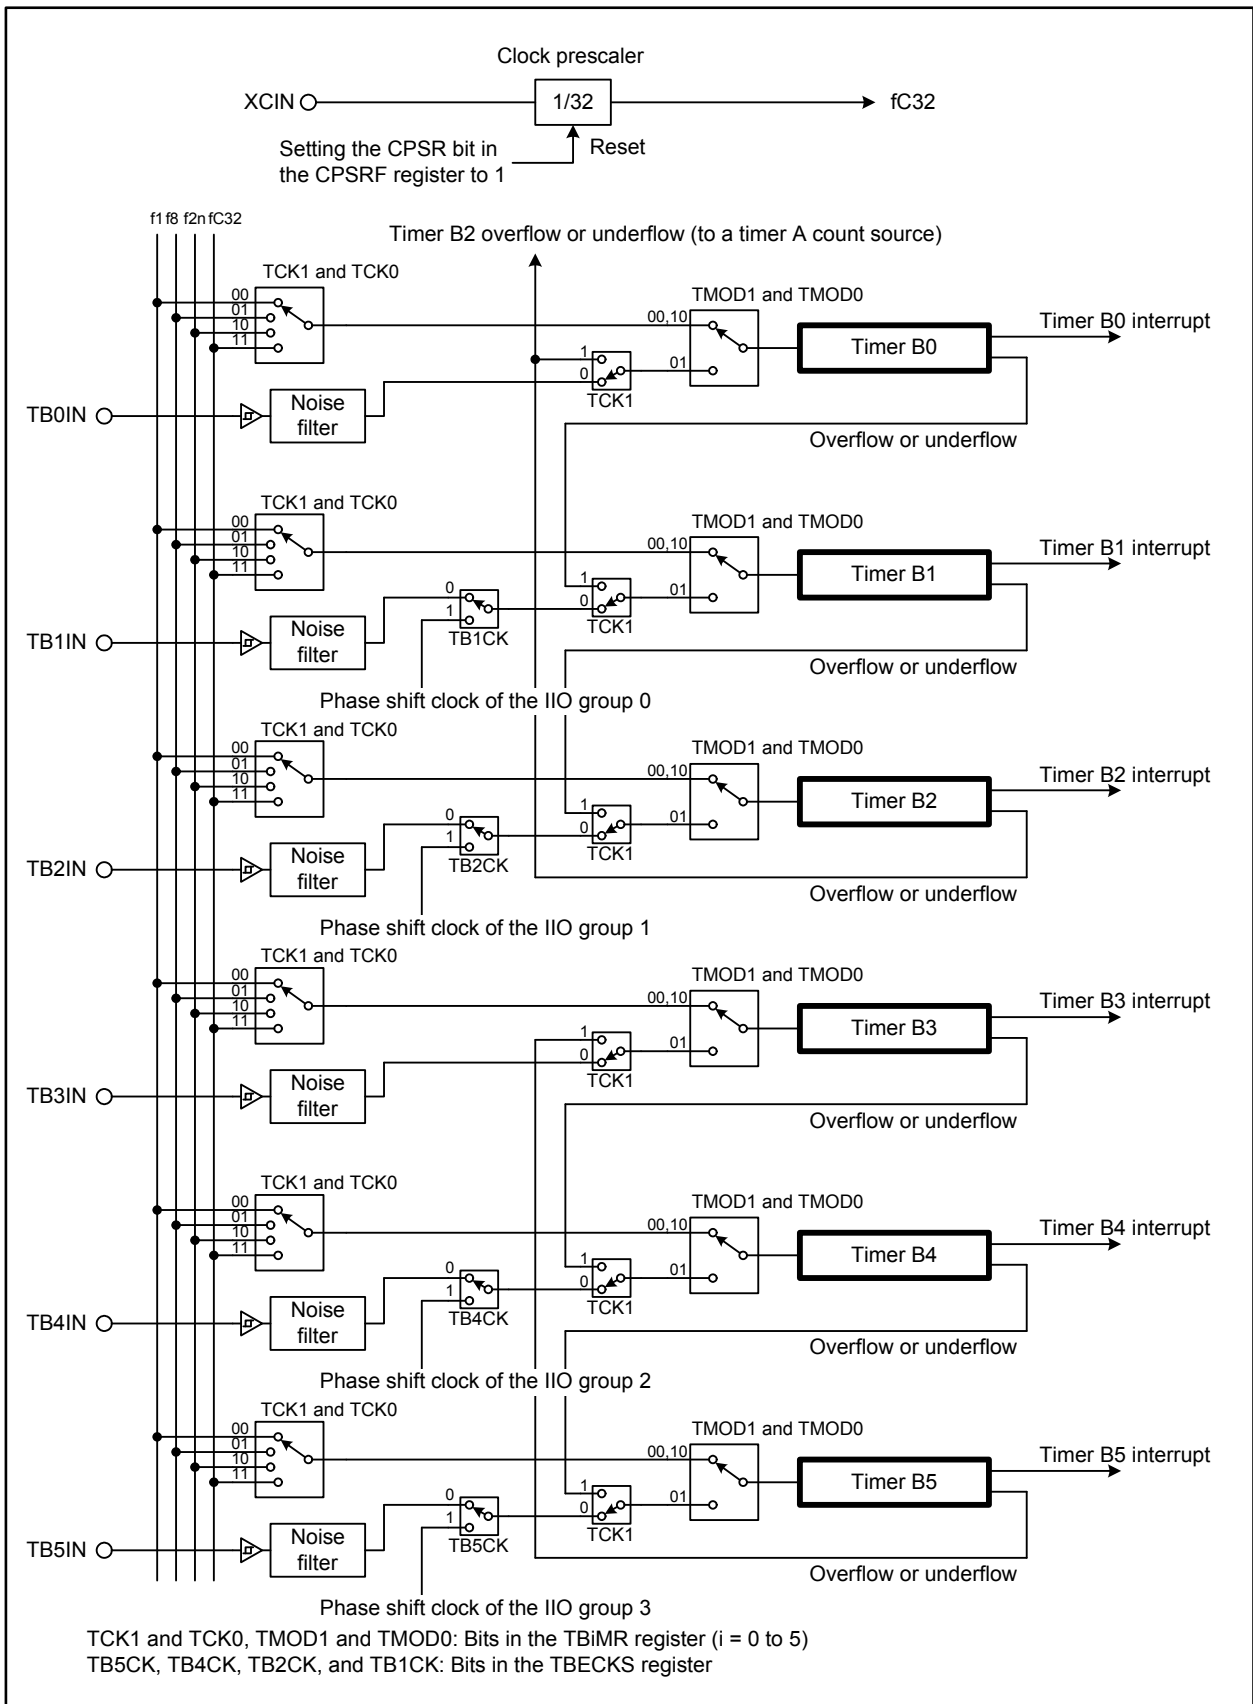

Figure 15.2   Timer B Configuration

15.1   Timer A

Figure 15.3 shows a block diagram of timer A and Figure 15.4 to Figure 15.10 show registers associated with timer A.

Timer A supports the four modes shown below. Timers A0 to A4 in any mode other than the event counter mode have the same function. Select a mode by setting bits TMOD1 and TMOD0 in the TAiMR register (i = 0 to 4).

  • Timer mode: The timer counts an internal count source
  • Event counter mode: The timer counts an external pulse or overflow and underflow of other timers
  • One-shot timer mode: The timer outputs pulses after a trigger input until the counter reaches 0000h
  • Pulse-width modulation mode: The timer successively outputs pulses of a given width

TAi	TAj	TAk
Timer A0	Timer A4	Timer A1
Timer A1	Timer A0	Timer A2
Timer A2	Timer A1	Timer A3
Timer A3	Timer A2	Timer A4
Timer A4	Timer A3	Timer A0

i = 0 to 4
Notes:
  1. The timer overflows or underflows.
  2. j = i - 1, or j = 4 if i = 0 (refer to the list on the right)
  3. k = i + 1, or k = 0 if i = 4 (refer to the list on the right)

TCK1 and TCK0, TMOD1 and TMOD0, MR2: Bits in the TAiMR register
TAiTGH and TAiTGL: Bits in the ONSF register (i = 0) or in the TRGSR register (i = 1 to 4)
TAiS: Bits in the TABSR register
TAiUD: Bits in the UDF register

Figure 15.3   Timer A Block Diagram

Timer Ai Register (i = 0 to 4) [1]

b15   b8 b7   b0

Symbol	Address	Reset Value
TA0 to TA2	0347h-0346h, 0349h-0348h, 034Bh-034Ah	Undefined
TA3, TA4	034Dh-034Ch, 034Fh-034Eh	Undefined

Mode	Function	Setting Range	RW
Timer Mode	Divides the count source by n+1 (n = setting value)	0000h to FFFFh	RW
Event Counter Mode	Divides the count source by FFFFh -n+1 (when incrementing) or by n+1 (when decrementing) (n = setting value) [2]	0000h to FFFFh	RW
One-shot Timer Mode	Divides the count source by n, then stops (n = setting value) [3]	0000h to FFFFh [4]	WO
Pulse-width Modulation Mode (16-bit PWM)	PWM period: $(2^{16} -1)$ / fj High level width of PWM pulse: n / fj (fj = count source frequency, n = setting value of the TAi register) [5]	0000h to FFFEh [4]	WO
Pulse-width Modulation Mode (8-bit PWM)	PWM period: $(2^8 -1) \times (m+1)$ / fj High level width of PWM pulse: (m+1)n / fj (fj = count source frequency, n = setting value of the upper byte in the TAi register, m = setting value of the lower byte in the TAi register) [5]	00h to FEh (upper byte) 00h to FFh (lower byte) [4]	WO

fj: f1, f8, f2n, fC32
Notes:
1. A 16-bit read/write access to this register should be performed.
2. The timer counts an external input pulse or overflow and underflow of other timers.
3. When the TAi register is set to 0000h, the timer counter does not start, and the TAi interrupt request is not generated.
4. Use the MOV instruction to set the TAi register.
5. When the TAi register is set to 0000h, the pulse-width modulator does not operate, the TAiOUT pin is held low, and the TAi interrupt request is not generated. The same restrictions apply in 8-bit pulse-width modulator mode if the upper byte in the TAi register is set to 00h.

15.1.1 Timer Mode

In timer mode, the timer counts an internally generated count source. Table 15.1 lists the specifications of timer mode. Figure 15.11 shows registers TA0MR to TA4MR in this mode.

Table 15.1   Timer Mode Specifications (i = 0 to 4)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement • When the timer counter underflows, the reload register value is reloaded into the counter to continue counting
Divide ratio	$\dfrac{1}{n+1}$ n: TAi register setting value, 0000h to FFFFh
Count start condition	The TAiS bit in the TABSR register is 1 (start counter)
Count stop condition	The TAiS bit in the TABSR register is 0 (stop counter)
Interrupt request generating timing	When the timer counter underflows
TAiIN pin function	Functions as a programmable I/O port or a gate input
TAiOUT pin function	Functions as a programmable I/O port or a pulse output
Read from timer	The TAi register indicates the counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (it is transferred to the counter at the next reload timing)

Other functions	• Gate function
	  Input signal to the TAiIN pin can control the count start/stop
	• Pulse output function
	  The polarity of the TAiOUT pin is inverted each time the timer counter underflows.
	  A low is output while the TAiS bit holds 0 (stop counter)

Figure 15.11 Registers TA0MR to TA4MR in Timer Mode

15.1.2 Event Counter Mode

In event counter mode, the timer counts an external signal or an overflow and underflow of other timers. Timers A2, A3, and A4 can count two-phase external signals. Table 15.2 lists the specifications in event count mode and Table 15.3 also lists the specifications when the timers use two-phase pulse signal processing. Figure 15.12 shows registers TA0MR to TA4MR in this mode.

Table 15.2 Event Counter Mode Specifications (without two-phase pulse signal processing) (i = 0 to 4)

Item	Specification
Count sources	• External signal applied to the TAiIN pin (valid edge is selectable by a program) • One of the following: the overflow and/or underflow signal of timer B2, the overflow and/or underflow signal of timer Aj (j = i - 1, or j = 4 if i = 0), or the overflow and/or underflow signal of timer Ak (k = i + 1, or k = 0 if i = 4)
Count operations	• Increment/decrement can be switched by an external signal or program • When the timer counter underflows or overflows, the reload register value is reloaded into the counter to continue counting. In a free-running count operation, the timer counter continues counting without reloading
Divide ratio	• $\dfrac{1}{FFFFh - n + 1}$ when incrementing • $\dfrac{1}{n + 1}$ when decrementing n: TAi register setting value, 0000h to FFFFh
Count start condition	The TAiS bit in the TABSR register is 1 (start counter)
Count stop condition	The TAiS bit in the TABSR register is 0 (stop counter)
Interrupt request generating timing	When the timer counter overflows or underflows
TAiIN pin function	Functions as a programmable I/O port or a count source input
TAiOUT pin function	Functions as a programmable I/O port, a pulse output, or an input for switching between increment/decrement
Read from timer	The TAi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (it is transferred to the counter at the next reload timing)
Other functions	• Free-running count function The reload register value is not reloaded even if the timer counter overflows or underflows • Pulse output function The polarity of the TAiOUT pin is inverted whenever the timer counter overflows or underflows. A low is output while the TAiS bit holds 0 (stop counter)

Table 15.3 Event Counter Mode Specifications (with two-phase pulse signal processing on timers A2 to A4) (i = 2 to 4)

Item	Specification
Count sources	Two-phase pulse signal applied to pins TAiIN and TAiOUT
Count operations	• Increment/decrement can be switched by a two-phase pulse signal • When the timer counter underflows or overflows, the reload register value is reloaded into the counter to continue counting. In a free-running count operation, the timer counter continues counting without reloading
Divide ratio	• $\dfrac{1}{FFFFh - n + 1}$ when incrementing • $\dfrac{1}{n + 1}$ when decrementing $\qquad n$: TAi register setting value, 0000h to FFFFh
Count start condition	The TAiS bit in the TABSR register is 1 (start counter)
Count stop condition	The TAiS bit in the TABSR register is 0 (stop counter)
Interrupt request generating timing	When the timer counter overflows or underflows
TAiIN pin function	A two-phase pulse input
TAiOUT pin function	A two-phase pulse input
Read from timer	The TAi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (it is transferred to the counter at the next reload timing)
Other functions [1]	• Normal processing operation (timers A2 and A3) While the input signal applied to the TAjOUT pin is held high, the timer increments on the rising edge of the TAjIN pin and decrements on the falling edge (j = 2 or 3) TAjOUT TAjIN IC IC IC DC DC DC IC: Increments DC: Decrements • Quadrupled processing operation (timers A3 and A4) When the input signal applied to the TAkOUT pin is held high on the rising edge of the TAkIN pin, the timer increments on both the rising and falling edges of pins TAkOUT and TAkIN (k = 3 or 4). When the signal is held high on the falling edge of the TAkIN pin, the timer decrements on both the rising and falling edges of pins TAkOUT and TAkIN TAkOUT TAkIN Increments on all edges / Decrements on all edges • Counter reset by Z-phase input (timer A3) The counter value is set to 0 by Z-phase input

Note:
1. Only timer A3 is available for any of the other functions. Timer A2 is exclusively for normal processing operations and timer A4 is for the quadrupled processing operation.

Notes:
1. Set bits TAiTGH and TAiTGL in the ONSF or TRGSR register to select the count source in event counter mode.
2. This bit setting is enabled only when an external signal is counted.
3. The timer decrements when the input signal to the TAiOUT pin is held low, and increments when the signal is held high.
4. The TCK1 bit is enabled only in the TA3MR register.
5. For two-phase pulse signal processing, set the TAjP bit in the UDF register to 1 (two-phase pulse signal processing enabled) and bits TAjTGH and TAjTGL to 00b (input to the TAjIN pin) (j = 2 to 4).

Figure 15.12 Registers TA0MR to TA4MR in Event Counter Mode

15.1.2.1   Counter Reset by Two-phase Pulse Signal Processing

A Z-phase input signal resets the timer counter when a two-phase pulse signal is being processed.
This function can be used under the following conditions: timer A3 event counter mode, two-phase
pulse signal processing, free-running count operation, and quadrupled processing. The Z-phase signal
is applied to the $\overline{INT2}$ pin.

When the TAZIE bit in the ONSF register is set to 1 (Z-phase input enabled), the timer counter can be
reset by Z-phase input. To reset the counter, set the TA3 register to 0000h beforehand.

A Z-phase signal applied to the $\overline{INT2}$ pin is detected on an edge. The edge polarity is selected using the
POL bit in the INT2IC register. The Z-phase signal should be input in order to have a pulse width of at
least one count source cycle for timer A3. Figure 15.13 shows the two-phase pulse (phases A and B)
and the Z-phase.

The timer counter is reset at the initial count source input after Z-phase input is detected. Figure 15.14
shows the counter reset timing.

When timer A3 overflows or underflows during a reset by the Z-phase input, two timer A3 interrupt
requests are successively generated. To avoid this, the timer A3 interrupt request should not be used
when using this function.
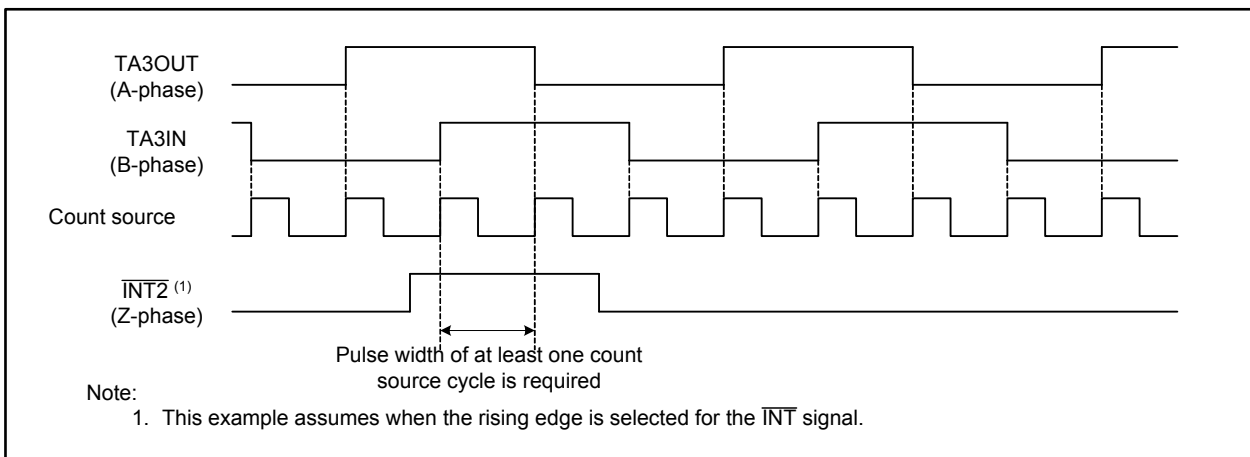

Figure 15.13 Two-phase Pulse (phases A and B) and Z-phase
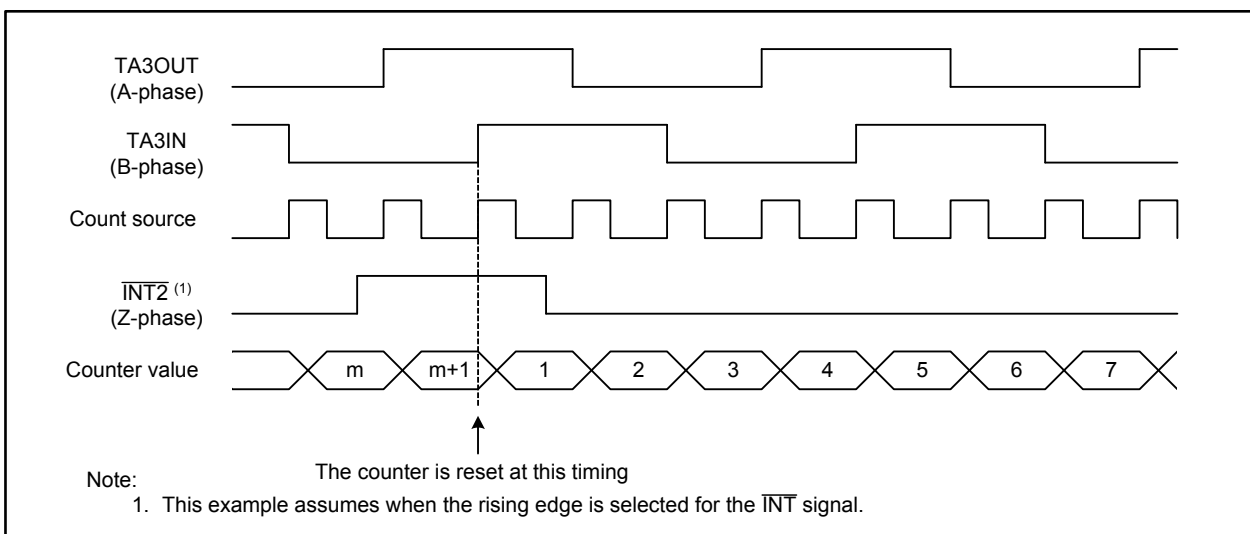

Figure 15.14 Counter Reset Timing

15.1.3   One-shot Timer Mode

In one-shot timer mode, the timer operates only once for each trigger. Table 15.4 lists specifications of one-shot timer mode. Once a trigger occurs, the timer starts and operates for a given period. Figure 15.15 shows registers TA0MR to TA4MR in this mode.

Table 15.4   One-shot Timer Mode Specifications (i = 0 to 4)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement • When the timer counter reaches 0000h, it stops running after the reload register value is reloaded • When a trigger occurs while counting, the reload register value is reloaded into the counter to continue counting
Divide ratio	$\dfrac{1}{n}$ n: TAi register setting value, 0000h to FFFFh (Note that the timer counter does not run if n = 0000h)
Count start conditions	The TAiS bit in the TABSR register is 1 (start counter) and any of following triggers occurs: • An external trigger applied to the TAiIN pin • One of the following: the overflow and/or underflow signal of timer B2, the overflow and/or underflow signal of timer Aj (j = i - 1, or j = 4 if i = 0), or the overflow and/or underflow signal of timer Ak (k = i + 1, or k = 0 if i = 4) • The TAiOS bit in the ONSF register is 1 (start the timer)
Count stop conditions	• The timer counter reaches 0000h and the reload register value is reloaded • The TAiS bit in the TABSR register is 0 (stop counter)
Interrupt request generating timing	When the timer counter reaches 0000h
TAiIN pin function	A programmable I/O port or a trigger input
TAiOUT pin function	A programmable I/O port or a pulse output
Read from timer	The TAi register indicates an undefined value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (it is transferred to the counter at the next reload timing)
Other function	• Pulse output function A low is output while the timer counter is stopped and a high is output while the timer counter is running

Note:
1. The MR1 bit setting is enabled only when bits TAiTGH and TAiTGL in the TRGSR register are set to 00b (input to the TAiIN pin). This bit can be set to either 0 or 1 when bits TAiTGH and TAiTGL are set to 01b (overflow or underflow of TB2), 10b (overflow or underflow of TAi), or 11b (overflow or underflow of TAi).

Figure 15.15 Registers TA0MR to TA4MR in One-shot Timer Mode

15.1.4   Pulse-width Modulation Mode

In pulse-width modulation mode, the timer outputs pulses of given width successively. Table 15.5 lists specifications of pulse-width modulation mode. The timer counter functions as either a 16-bit or 8-bit pulse-width modulator. Figure 15.16 shows registers TA0MR to TA4MR in this mode. Figures 15.17 and 15.18 show operation examples of 16-bit and 8-bit pulse-width modulators.

Table 15.5   Pulse-width Modulation Mode Specifications (i = 0 to 4)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement (the timer counter functions as an 8-bit or a 16-bit pulse-width modulator) • The reload register value is reloaded on the rising edge of a PWM pulse to continue counting • The timer is not affected by a trigger that occurs while the counter is running
16-bit PWM	• High level width: $\dfrac{n}{fj}$ n: TAi register setting value, 0000h to FFFEh fj: Count source frequency • Period: fixed to $\dfrac{2^{16}-1}{fj}$

8-bit PWM	• High level width: $\dfrac{n \times (m+1)}{fj}$
	
	• Period: $\dfrac{(2^{8}-1) \times (m+1)}{fj}$
	
	  n: Upper byte of the TAi register setting value, 00h to FEh
	  m: Lower byte of the TAi register setting value, 00h to FFh

Count start conditions	• The TAiS bit in the TABSR register is 1 (start counter) • The TAiS bit is 1 and an external trigger is applied to the TAiIN pin • The TAiS bit is 1 and any of following triggers occurs: the overflow and/or underflow signal of timer B2, the overflow and/or underflow signal of timer Aj (j = i - 1, or j = 4 if i = 0), or the overflow and/or underflow signal of timer Ak (k = i + 1, or k = 0 if i = 4)
Count stop condition	The TAiS bit in the TABSR register is 0 (stop counter)
Interrupt request generating timing	On the falling edge of the PWM pulse
TAiIN pin function	A programmable I/O port or trigger input
TAiOUT pin function	A pulse output
Read from timer	The TAi register indicates an undefined value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TAi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TAi register is written to the reload register (it is transferred to the counter at the next reload timing)

Note:
1. The MR1 bit setting is enabled only when bits TAiTGH and TAiTGL in the TRGSR register are set to 00b (input to the TAiIN pin). This bit can be set to either 0 or 1 when bits TAiTGH and TAiTGL are set to 01b (overflow or underflow of TB2), 10b (overflow or underflow of TAi), or 11b (overflow or underflow of TAi).

Figure 15.16 Registers TA0MR to TA4MR in Pulse-width Modulation Mode

When the reload register is 0003h and an external trigger (the rising edge of an input signal applied to the TAiIN pin) is selected.

$1/fj \times (2^{16}-1)$

Count source

Input signal to the TAiIN pin

No trigger occurs by this signal

$1/fj \times n$ [1]

PWM pulse output from TAiOUT pin

IR bit in the TAiIC register

Set to 0 by an interrupt request acceptance or by a program

i = 0 to 4
fj: Count source frequency
(f1, f8, f2n, fC32)

Note:
1. n is a value from 0000h to FFFEh.

Figure 15.17 16-bit Pulse-width Modulator Operation

When the upper byte of the reload register is 02h, the lower byte is 02h and an external trigger (the falling edge of an input signal applied to the TAiIN pin) is selected.

$1/fj \times (m + 1) \times (2^8 - 1)$

Count source [1]

Input signal applied to the TAiIN pin

$1/fj \times (m + 1)$ [1]

Underflow signal of 8-bit prescaler [2]

$1/fj \times (m + 1) \times n$ [3]

PWM pulse output from the TAiOUT pin

IR bit in the TAiIC register

Set to 0 by an interrupt request acceptance or by a program

i = 0 to 4
fj: Count source frequency
(f1, f8, f2n, fC32)

Notes:
1. The 8-bit prescaler counts a count source.
2. The 8-bit pulse-width modulator counts underflow signals of the 8-bit prescaler.
3. m is a value from 00h to FFh, and n is a value from 00h to FEh.

Figure 15.18 8-bit Pulse-width Modulator Operation

15.2   Timer B

Figure 15.19 shows a block diagram of timer B, and Figure 15.20 to Figure 15.23 show registers associated with timer B.

Timer B supports the three modes shown below. Select a mode by setting bits TMOD1 and TMOD0 in the TBiMR register (i = 0 to 5).

- Timer mode: The timer counts an internal count source.
- Event counter mode: The timer counts an external pulse or an overflow and underflow of other timers.
- Pulse period/pulse-width measure mode: The timer measures the pulse period or pulse width of an external signal.

Figure 15.19 Timer B Block Diagram

15.2.1 Timer Mode

In timer mode, the timer counts an internally generated count source. Table 15.6 lists specifications of timer mode. Figure 15.24 shows registers TB0MR to TB5MR in this mode.

Table 15.6   Timer Mode Specifications (i = 0 to 5)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Decrement • When the timer counter underflows, the reload register value is reloaded into the counter to continue counting
Divide ratio	$\dfrac{1}{n+1}$ n: TBi register setting value, 0000h to FFFFh
Count start condition	The TBiS bit in the TABSR or TBSR register is 1 (start counter)
Count stop condition	The TBiS bit in the TABSR or TBSR register is 0 (stop counter)
Interrupt request generating timing	When the timer counter underflows
TBiIN pin function	Functions as a programmable I/O port
Read from timer	The TBi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TBi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TBi register is written to the reload register (it is transferred to the counter at the next reload timing)

15.2.2   Event Counter Mode

In event counter mode, the timer counts an external signal or the overflow or underflow of other timers. Table 15.7 lists specifications of event counter mode. Figure 15.25 shows the TBiMR register in this mode (i = 0 to 5).

Table 15.7   Event Counter Mode Specifications (i = 0 to 5)

Item	Specification
Count sources	• External signal applied to the TBiIN pin (valid edge is selectable among the falling edge, the rising edge, or both) • The overflow or underflow signal of TBj (j = i - 1; j = 2 if i = 0; or j = 5 if i = 3) • Phase shift clock of the intelligent I/O group k (k = i - 1 if i = 1 or 2; k = i - 2 if i = 4 or 5)
Count operations	• Decrement • When the timer counter underflows, the reload register value is reloaded into the counter to continue counting
Divide ratio	$\dfrac{1}{n+1}$ n: TBi register setting value, 0000h to FFFFh
Count start condition	The TBiS bit in the TABSR or TBSR register is 1 (start counter)
Count stop condition	The TBiS bit in the TABSR or TBSR register is 0 (stop counter)
Interrupt request generation timing	When the timer counter underflows
TBiIN pin function	Functions as a programmable I/O port or count source input
Read from timer	The TBi register indicates a counter value
Write to timer	• While the timer counter is stopped or before the initial count source is input after starting to count, the value written to the TBi register is written to both the reload register and the counter • While the timer counter is running, the value written to the TBi register is written to the reload register (it is transferred to the counter at the next reload timing)

TB4CK	Timer B4 Event Clock Select Bit	0: Select TB4IN 1: Select phase shift clock of the intelligent I/O group 2	RW
TB5CK	Timer B5 Event Clock Select Bit	0: Select TB5IN 1: Select phase shift clock of the intelligent I/O group 3	RW
— (b7-b4)	Reserved	Should be written with 0	RW

Note:
1. If a clock selected by this register is also selected by the TCK1 bit in the TBiMR register (i = 1, 2, 4, or 5), that clock functions as the event clock for timer Bi.

Figure 15.26 TBECKS Register

15.2.3   Pulse Period/Pulse-width Measure Mode

In pulse period/pulse-width measure mode, the timer measures the pulse period or pulse width of an external signal. Table 15.8 lists specifications of the pulse period/pulse-width measure mode. Figure 15.27 shows registers TB0MR to TB5MR in this mode. Figures 15.28 and 15.29 show an operation example of pulse period measurement and pulse-width measurement, respectively.

Table 15.8   Pulse Period/Pulse-width Measure Mode Specifications (i = 0 to 5)

Item	Specification
Count sources	f1, f8, f2n, or fC32
Count operations	• Increment • The counter value is transferred to the reload register on the valid edge of a pulse to be measured, then it is set to 0000h to resume counting
Count start condition	The TBiS bit in the TABSR or TBSR register is 1 (start counter)
Count stop condition	The TBiS bit in the TABSR or TBSR register is 0 (stop counter)
Interrupt request generating timing	• On the valid edge of a pulse to be measured [1] • When the timer counter overflows (when the MR3 bit in the TBiMR register becomes 1 (overflow)) [2]
TBiIN pin function	A pulse input to be measured
Read from timer	The TBi register indicates a reload register value (measurement results) [3]
Write to timer	The value written to the TBi register is written to neither the reload register nor the counter

Notes:
1. No interrupt request is generated when the pulse to be measured is applied on the initial valid edge after the timer counter starts.
2. While the TBiS bit is 1 (start counter), after the MR3 bit becomes 1 (overflow) and at least one count source cycle has elapsed, a write operation to the TBiMR register sets the MR3 bit to 0 (no overflow).
3. The TBi register indicates an undefined value until the pulse to be measured is applied on the second valid edge after the timer counter starts.

Timer Bi Mode Register (i = 0 to 5) (pulse period/pulse-width measure mode)

TB3MR to TB5MR	031Bh, 031Ch, 031Dh	00XX 0000b

Bit Symbol	Bit Name	Function	RW
TMOD0	Operating Mode Select Bit	b1 b0 1 0 : Pulse period/pulse-width measure mode	RW
TMOD1			RW
MR0	Measure Mode Select Bit [1]	b3 b2 0 0 : Pulse period measurement 1 0 1 : Pulse period measurement 2 1 0 : Pulse-width measurement 1 1 : Do not use this combination	RW
MR1			RW
MR2	In registers TB0MR and TB3MR: Reserved; should be written with 0		RW
	In registers TB1MR, TB2MR, TB4MR, and TB5MR: No register bit; should be written with 0 and read as undefined value		—
MR3	Timer Bi Overflow Flag [2]	0: No overflow 1: Overflow	RO
TCK0	Count Source Select Bit	b7 b6 0 0 : f1 0 1 : f8 1 0 : f2n 1 1 : fC32	RW
TCK1			RW

Notes:
1. The measure modes selected by setting bits MR1 and MR0 are as follows:
   Pulse period measurement 1 (bits MR1 and MR0 = 00b):
     Measures between a falling edge and the next falling edge of a pulse
   Pulse period measurement 2 (bits MR1 and MR0 = 01b):
     Measures between a rising edge and the next rising edge of a pulse
   Pulse-width measurement (bits MR1 and MR0 = 10b):
     Measures between a falling edge and the next rising edge of a pulse and between the rising edge and the next falling edge of the pulse
2. The MR3 bit is undefined when the timer is reset.
   While the TBiS bit in the TABSR or TBSR register is 1 (start counter), after the MR3 bit becomes 1 and at least one count source cycle has elapsed, a write operation to the TBiMR register sets the MR3 bit to 0. The MR3 bit cannot be set to 1 by a program.

Figure 15.27 Registers TB0MR to TB5MR in Pulse Period/Pulse-width Measure Mode
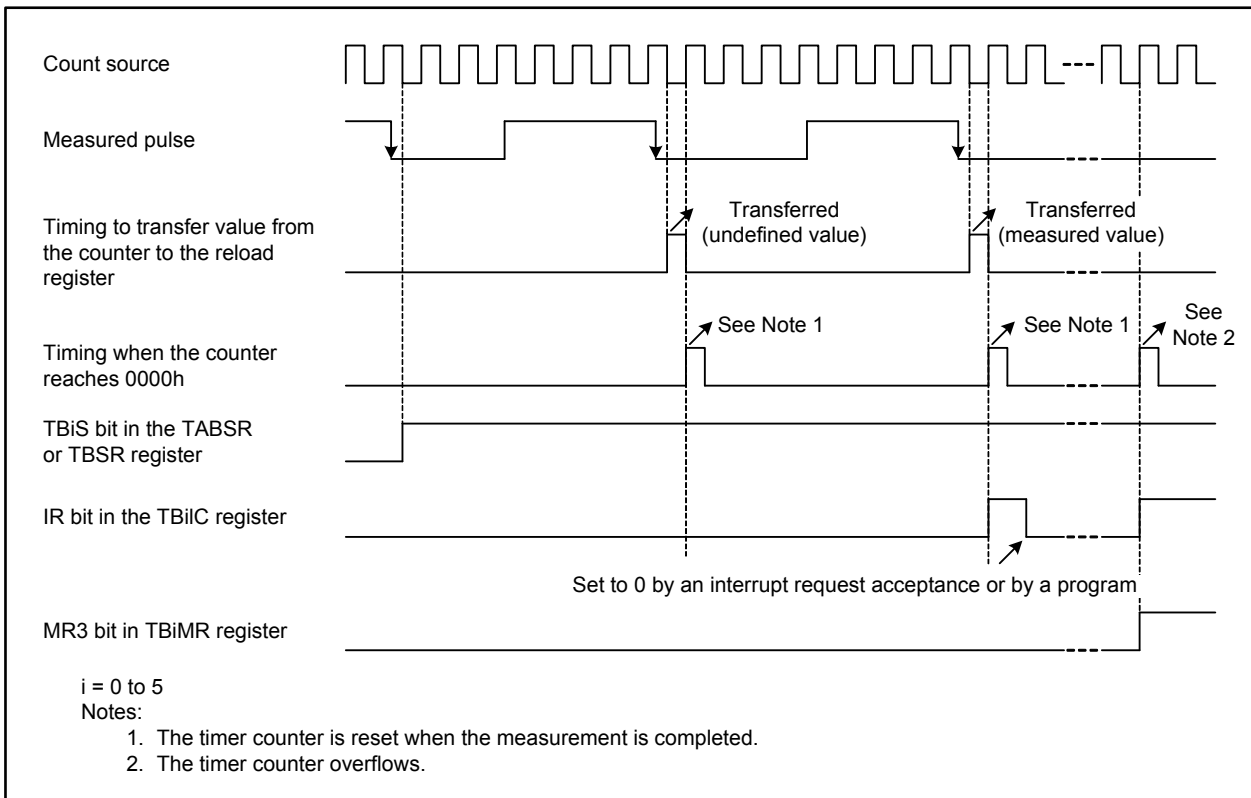

Figure 15.28 Operation Example in Pulse Period Measurement
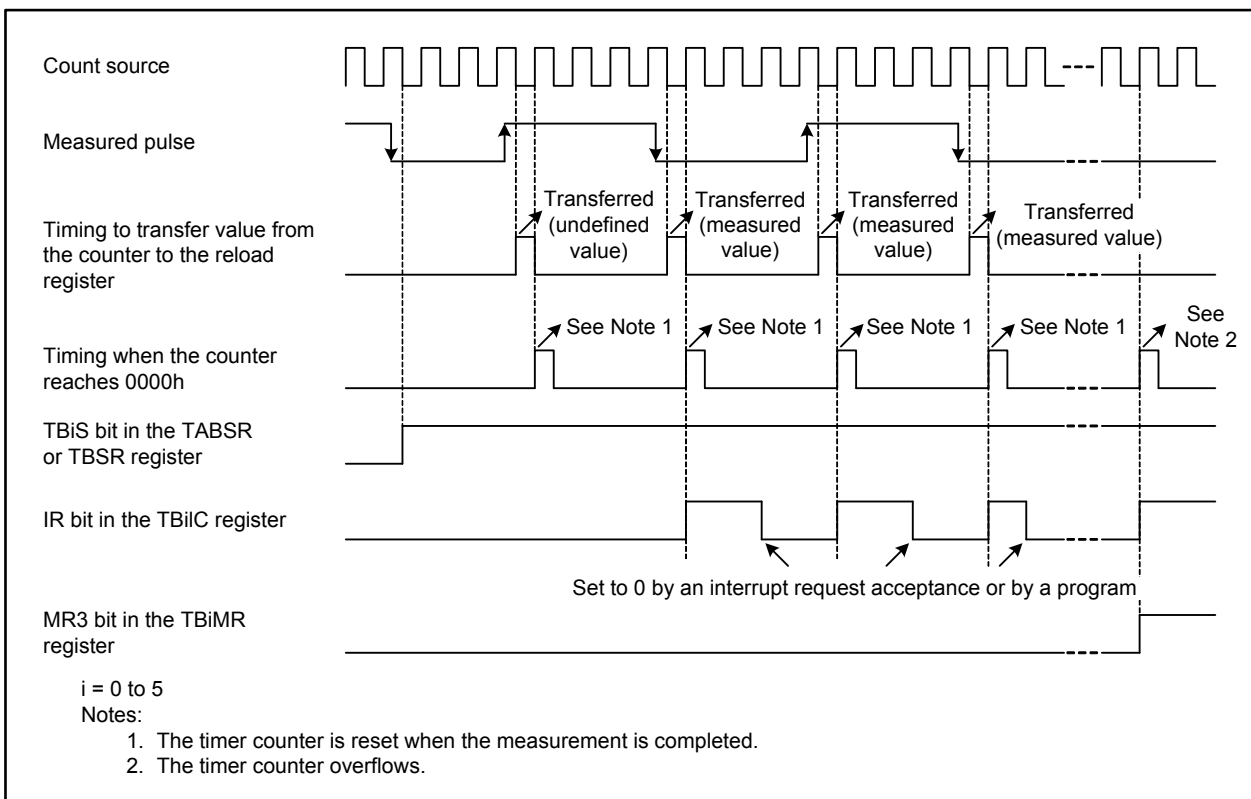

Figure 15.29 Operation Example in Pulse-width Measurement

15.3   Notes on Timers

15.3.1   Timer A and Timer B

All timers are stopped after a reset. To restart timers, configure parameters such as operating mode, count source, and counter value, then set the TAiS bit or TBjS bit in the TABSR or TBSR register to 1 (count starts) (i = 0 to 4; j = 0 to 5).

The following registers and bits should be set while the TAiS bit or TBjS bit is 0 (count stops):
- Registers TAiMR and TBjMR
- UDF register
- Bits TAZIE, TA0TGL, and TA0TGH in the ONSF register
- TRGSR register

15.3.2   Timer A

15.3.2.1   Timer Mode

- While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

15.3.2.2   Event Counter Mode

- While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read if the timer counter underflows or 0000h if overflows while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

15.3.2.3   One-shot Timer Mode

- If the TAiS bit in the TABSR register is set to 0 (count stops) while the timer counter is running, the following operations are performed:
  - The timer counter stops and the setting value of the TAi register is reloaded.
  - A low signal is output at the TAiOUT pin.
  - The IR bit in the TAiIC register becomes 1 (interrupts requested) after one CPU clock cycle.

- The one-shot timer is operated by an internal count source. When the trigger is an input to the TAiIN pin, the signal is output with a maximum one count source clock delay after a trigger input to the TAiIN pin.

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt, set the IR bit to 0 after one of the settings below is done:
  - Select one-shot timer mode after a reset.
  - Switch operating modes from timer mode to one-shot timer mode.
  - Switch operating modes from event counter mode to one-shot timer mode.

- If a retrigger occurs while counting, the timer counter decrements by one, reloads the setting value of the TAi register, and then continues counting. To generate a retrigger while counting, wait at least one count source cycle after the last trigger is generated.

- When an external trigger input is selected to start counting in timer A one-shot mode, do not provide an external retrigger for 300 ns before the timer counter reaches 0000h. Otherwise, it may stop counting.

15.3.2.4   Pulse-width Modulation Mode

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt, set the IR bit to 0 after one of the settings below is done (i = 0 to 4):
    - Select pulse-width modulation mode after a reset.
    - Switch operating modes from timer mode to pulse-width modulation mode.
    - Switch operating modes from event counter mode to pulse-width modulation mode.

- If the TAiS bit in the TABSR register is set to 0 (count stops) while PWM pulse is output, the following operations are performed:
    - The timer counter stops.
    - The output level at the TAiOUT pin changes from high to low. The IR bit becomes 1.
    - When a low signal is output at the TAiOUT pin, it does not change. The IR bit does not change, either.

15.3.3   Timer B

15.3.3.1   Timer Mode and Event Counter Mode

- While the timer counter is running, the TBj register indicates a counter value at any given time (j = 0 to 5). However, FFFFh is read while reloading is in progress. When a value is set to the TBj register while the timer counter is stopped, if the TBj register is read before the count starts, the set value is read.

15.3.3.2   Pulse Period/Pulse-width Measure Mode

- To set the MR3 bit in the TBjMR register to 0 (no overflow), write the TBjMR register after the MR3 bit becomes 1 (overflow) and at least one count source cycle has elapsed while the TBjS bit in the TABSR or TBSR register is 1 (start counter).

- Use the IR bit in the TBjIC register to detect overflow. The MR3 bit is used only to determine an interrupt request source within the interrupt handler.

- The counter value is undefined when the timer counter starts. Therefore, the timer counter may overflow before a measured pulse is applied on the initial valid edge and cause a timer Bj interrupt request to be generated.

- When the measured pulse is applied on the initial valid edge after the timer counter starts, an undefined value is transferred to the reload register. At this time, a timer Bj interrupt request is not generated.

- The IR bit may become 1 (interrupt requested) by changing bits MR1 and MR0 in the TBjMR register after the timer counter starts. However, if the same value is rewritten to bits MR1 and MR0, the IR bit does not change.

- Pulse width is continuously measured in pulse-width measure mode. Whether the measurement result is high-level width or not is determined by a program.

- When an overflow occurs at the same time a pulse is applied on the valid edge, this pulse is not recognized since an interrupt request is generated only once. Do not let an overflow occur in pulse period measure mode.

- In pulse-width measure mode, determine whether an interrupt source is a pulse applied on the valid edge or an overflow by reading the port level in the timer Bj interrupt handler.

16. Three-phase Motor Control Timers

A three-phase motor driving waveform can be output using timers A1, A2, A4, and B2. The three-phase motor control timers are enabled by setting the INV02 bit in the INVC0 register to 1. Timer B2 is used for carrier wave control, and timers A1, A2, and A4 for three-phase PWM output (U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$) control. Table 16.1 lists the specifications of the three-phase motor control timers and Figure 16.1 shows its block diagram. Figures 16.2 to 16.6 show registers associated with this function.

Table 16.1   Specifications for Three-phase Motor Control Timers

Item	Specification
Three-phase PWM waveform output pins	Six pins: U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$
Forced cutoff [1]	A low input to the $\overline{NMI}$ pin

Timers	Timers A4, A1, and A2 are used in one-shot timer mode:
	    Timer A4 is used for U- and $\overline{U}$-phase waveform control
	    Timer A1 is used for V- and $\overline{V}$-phase waveform control
	    Timer A2 is used for W- and $\overline{W}$-phase waveform control
	Timer B2 is used in timer mode
	    Carrier wave cycle control
	Dead time timer (three 8-bit timers share a reload register):
	    Dead time control

Output waveforms	Triangular wave modulation and sawtooth wave modulation • Output of a high or a low waveform for one cycle • Separately settable levels of high side and low side

Carrier wave periods	Triangular wave modulation: count source × (m + 1) × 2
	Sawtooth wave modulation: count source × (m + 1)
	    m: TB2 register setting value from 0000h to FFFFh
	    Count source: f1, f8, f2n, or fC32

Three-phase PWM output width	Triangular wave modulation: count source × n × 2
	Sawtooth wave modulation: count source × n
	    n: Setting value of registers TA4, TA1, and TA2 (registers TA4, TA41,
	        TA1, TA11, TA2, and TA21 when the INV11 bit in the INVC1 register
	        is 1) from 0001h to FFFFh
	    Count source: f1, f8, f2n, or fC32

Dead time (width)	Count source × p or no dead time
	    p: DTT register setting value from 01h to FFh
	    Count source: f1 or f1 divided by 2

Active level	Selectable either active high or active low
Simultaneous conduction prevention	Function to detect simultaneous turn-on signal outputs, function to disable signal output when simultaneous turn-on signal outputs are detected
Interrupt frequency	Selectable from one through 15 time-carrier wave cycle-to-cycle basis for the timer B2 interrupt

Note:
1. Forced cutoff by a signal input to the $\overline{NMI}$ pin can be performed when the PM24 bit in the PM2 register is 1 (NMI enabled), the SDE bit in the IOBC register is 1 (shutdown enabled), the INV02 bit in the INVC0 register is 1 (three-phase motor control timers used), and the INV03 bit is 1 (three-phase motor control timer output enabled).

Figure 16.1   Block Diagram for Three-phase Motor Control Timers

Three-phase PWM Control Register 0 [1]

	b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value
		INVC0	0308h	0000 0000b

Bit Symbol	Bit Name	Function	RW
INV00	ICTB2 Count Condition Select Bit [2]	b1 b0 0 X : The underflow of timer B2 1 0 : The underflow of timer B2 when the reload control signal for timer A1 is 0 [3]	RW
INV01		1 1 : The underflow of timer B2 when the reload control signal for timer A1 is 1 [3, 4]	RW
INV02	Three-phase Motor Control Timers Select Bit	0: Do not use this function 1: Use this function [5, 6, 7]	RW
INV03	Three-phase Motor Control Timer Output Control Bit	0: Disables the three-phase motor control timer output [7] 1: Enables the three-phase motor control timer output [8]	RW
INV04	Simultaneous Conduction Prevention Bit	0: Ignores simultaneous turn-on signal output 1: Disables simultaneous turn-on signal output	RW
INV05	Simultaneous Conduction Detection Flag	0: Not detected 1: Detected [9]	RO
INV06	Modulation Mode Select Bit	0: Triangular wave modulation mode 1: Sawtooth wave modulation mode [10]	RW
INV07	Software Trigger Select Bit	A transfer trigger is generated when this bit is set to 1. When the INV06 bit is 1, another trigger to the dead time timer is also generated. This bit is read as 0	RW

Notes:
1. Set this register after setting the PRC1 bit in the PRCR register to 1 (write enabled). Also, rewrite bits INV00 to INV02 and INV06 while timers A1, A2, A4, and B2 are stopped.
2. This bit is enabled when the INV11 bit in the INVC1 register is 1 (three-phase mode 1). When the INV11 bit is 0 (three-phase mode 0), the ICTB2 counter increments by one each time timer B2 underflows irrespective of the INV00 and INV01 bit settings.
3. Set the ICTB2 register before setting the INV01 bit to 1. Also, set the TA1S bit in the TABSR register to 1 before the initial timer B2 underflow occurs.
4. When the INV00 bit is 1, the first interrupt occurs when timer B2 underflows n-1 times (n is the value set in the ICTB2 counter). Subsequent interrupts occur every n times timer B2 underflows.
5. Set the INV02 bit to 1 to operate the dead time timer, U-, V-, and W-phase output control circuits, and the ICTB2 counter.
6. After setting the INV02 bit to 1, pins should be configured first by the IOBC register then by the output function select registers.
7. When the INV02 bit is set to 1 and the INV03 bit is set to 0, pins U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$, even when they are assigned to other peripheral functions, become high-impedance.
8. The INV03 bit becomes 0 when any of the following occurs:
   - Reset
   - Signals of both the high and low sides are simultaneously switched to active when the INV04 bit is 1.
   - The INV03 bit is set to 0 by a program.
   - The $\overline{NMI}$ pin goes from high to low when the PM24 bit in the PM2 register is 1 (NMI enabled) and the SDE bit in the IOBC register is 1 (shutdown enabled).
9. This bit cannot be set to 1 by a program. Set the INV04 bit to 0 to set this bit to 0.
10. When the INV06 bit is 1, set the INV11 bit in the INVC1 register to 0 (three-phase mode 0) and the PWCON bit in the TB2SC register to 0 (timer B2 register reloaded when timer B2 underflows).

Figure 16.2   INVC0 Register

Three-phase PWM Control Register 1 [1]

b7 b6 b5 b4 b3 b2 b1 b0

| | | | | | | | |

Symbol — INVC1
Address — 0309h
Reset Value — 0000 0000b

Bit Symbol	Bit Name	Function	RW
INV10	Timers A1, A2, and A4 Start Trigger Select Bit	0: The underflow of timer B2 1: The underflow of timer B2 and a write operation to the TB2 register	RW
INV11	Timers A1-1, A2-1, and A4-1 Control Bit	0: Three-phase mode 0 [2, 3] 1: Three-phase mode 1	RW
INV12	Dead Time Timer Count Source Select Bit	0: f1 1: f1 divided-by-2	RW
INV13	Carrier Wave Detection Flag [4]	0: Timer A1 reload control signal is 0 1: Timer A1 reload control signal is 1	RO
INV14	Active Level Control Bit	0: Active low output 1: Active high output	RW
INV15	Dead Time Disable Bit	0: Enables dead time 1: Disables dead time	RW
INV16	Dead Time Timer Trigger Select Bit	0: Falling edge of a one-shot pulse of timer (A4, A1, and A2) [5] 1: Rising edge of the three-phase output shift register (phases U, V, and W)	RW
— (b7)	Reserved	Should be written with 0	RW

Notes:

1. Set this register after setting the PRC1 bit in the PRCR register to 1 (write enabled). Also, rewrite this register while timers A1, A2, A4, and B2 are stopped.
2. Set the INV11 bit to 0 when the INV06 bit in the INVC0 register is 1 (sawtooth wave modulation mode).
3. Set the PWCON bit in the TB2SC register to 0 (timer B2 register reloaded if timer B2 underflows) when the INV11 bit is 0.
4. This bit setting is enabled when the INV06 bit is 0 (triangular wave modulation mode) and the INV11 bit is 1.
5. Set the INV16 bit to 1 when the following conditions are all met:
   - The INV15 bit is 0.
   - The Dij bit has a different value from the DiBj bit whenever the INV03 bit is 1 (enables the three-phase motor control timer output); the high- and low-side output signals always have inverse levels on periods other than dead time (i = U, V, or W; j = 0, 1).
   Set the INV16 bit to 0 when the conditions above are not met.

Figure 16.3   INVC1 Register

Three-phase Output Buffer Control Register [1]

	b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value
		IOBC	40097h	0XXX XX0Xb

Bit Symbol	Bit Name	Function	RW
— (b0)	No register bit; should be written with 0 and read as undefined value		—
SDE	Three-phase Output Pin Shutdown Enable Bit	0: Disable shutdown 1: Enable shutdown	RW
— (b6-b2)	No register bits; should be written with 0 and read as undefined value		—
TBSOUT	Three-phase Output Pin Select Bit [2]	0: Use pins U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$ of ports P7 and P8 1: Use pins U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$ of port P3	RW

Notes:
1. Set this register after setting the PRC1 bit in the PRCR register to 1 (write enabled).
2. Set this bit after setting the INV02 bit in the INVC0 register to 1. Then, set the output function select register of corresponding port. When the INV03 bit in the INVC0 register is 0, output pins for the three-phase motor control timers become high-impedance by the output enable control of output buffers. However, the output enable cannot be controlled only by the output function select register when more than two ports are assigned for output. Thus, a three-state output buffer should be selected using the TBSOUT bit.

Figure 16.4   IOBC Register

16.1   Modulation Modes of Three-phase Motor Control Timers

The three-phase motor control timers support two modulation modes: triangular wave modulation mode and sawtooth wave modulation mode. The triangular wave modulation mode has two modes: three-phase mode 0 and three-phase mode 1. Table 16.2 lists bit settings and characteristics of each mode.

Table 16.2   Modulation Modes

Item	Triangular Wave Modulation Mode		Sawtooth Wave Modulation Mode
	Three-phase mode 0	Three-phase mode 1	(Three-phase mode 0)
Bit settings	INV06 is 0, INV11 is 0, PWCON is 0	INV06 is 0, INV11 is 1	INV06 is 1, INV11 is 0, PWCON is 0
Waveform	Triangular wave		Sawtooth wave
Registers TA11, TA21, and TA41	Not used	Used	Not used
Timing to transfer data from registers IDB0 and IDB1 to the three-phase output shift register	Only once when a transfer trigger [1] occurs after setting registers IDB0 and IDB1		Whenever a transfer trigger [1] occurs
Timing to trigger the dead time timer when the INV16 bit is 0	On the falling edge of a one-shot pulse of timers A1, A2, and A4		When a transfer trigger occurs, or on the falling edge of a one-shot pulse of timers A1, A2, and A4
Bits INV00 and INV01 in the INVC0 register	Disabled. The ICTB2 counter increments each time timer B2 underflows, irrespective of the INV00 and INV01 bit settings	Enabled	Disabled. The ICTB2 counter increments each time timer B2 underflows, irrespective of the INV00 and INV01 bit settings
INV13 bit	Disabled	Enabled	Disabled

Note:
1. The transfer trigger is a timer B2 underflow, a write operation to the INV07 bit, or a write operation to the TB2 register when the INV10 bit is 1.

16.2   Timer B2

Timer B2, which operates in timer mode, is used for carrier wave control in the three-phase motor control timers.

Figures 16.7 and 16.8 show registers TB2 and TB2MR in this function, respectively. Figure 16.9 shows the TB2SC register which switches timing to change the carrier wave frequency in three-phase mode 1.
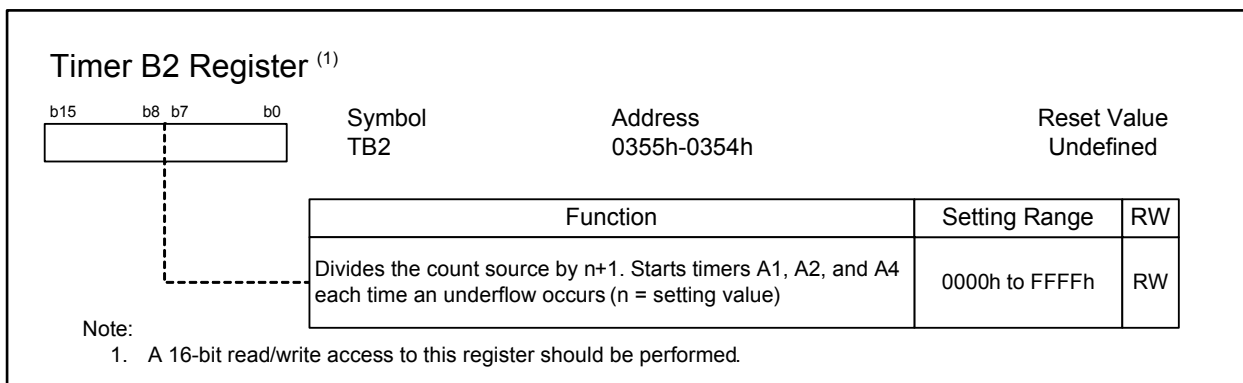

Timer B2 Register [1]

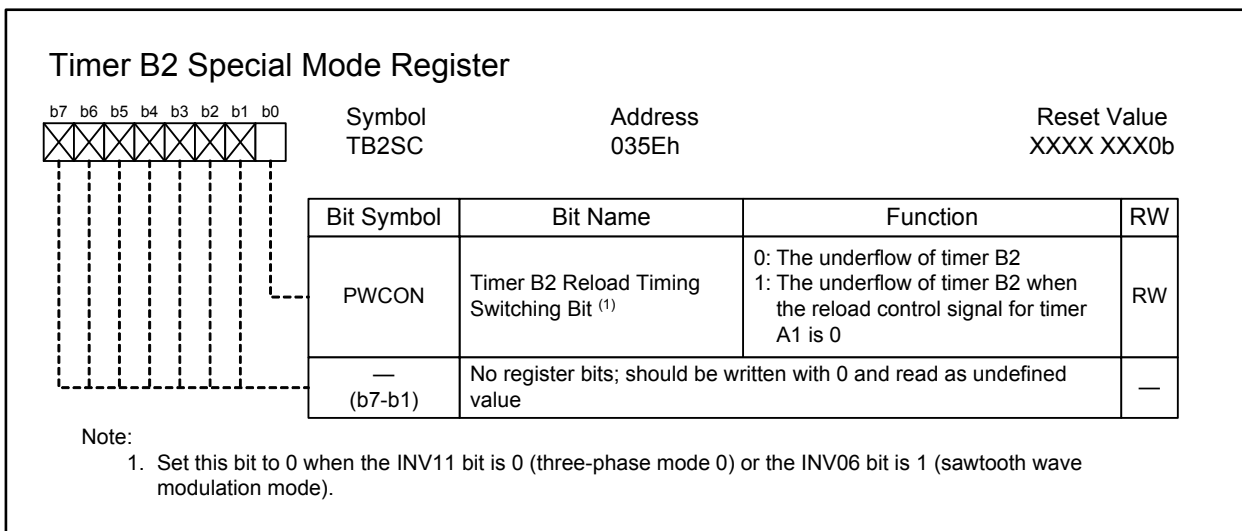

Figure 16.9   TB2SC Register

16.3   Timers A4, A1, and A2

Timers A4, A1, and A2 are used for three-phase PWM output (U, $\overline{U}$, V, $\overline{V}$, W, and $\overline{W}$) control when using the three-phase motor control timers.

These timers should be operated in one-shot timer mode. Every time timer B2 underflows, a trigger is input to timers A4, A1, and A2 to generate a one-shot pulse. If the values of registers TA4, TA1, and TA2 are rewritten every time a timer B2 interrupt occurs, the duty cycle of the PWM waveform can be varied.

In three-phase mode 1, the value of registers TAi and TAi-1 is alternately reloaded to the counter at each timer B2 interrupt, which halves the timer B2 interrupt frequency (i = 4, 1, 2).

Figure 16.10 shows registers TA1, TA2, TA4, TA11, TA21, and TA41 in the three-phase motor control timers. Figure 16.11 shows registers TA1M, TA2M, TA4M, TA11M, TA21M, and TA41M in this function. Figure 16.12 shows registers TA1MR, TA2MR, and TA4MR in this function. Figures 16.13 and 16.14 show registers TRGSR and TABSR, respectively, in this function.

16.4   Simultaneous Conduction Prevention and Dead Time Timer

The three-phase motor control timers offer two ways to avoid shoot-through, which occurs when high-side and low-side transistors are simultaneously turned on.

One is "simultaneous turn-on signal output disable function". This function prevents high-side and low-side transistors from being inadvertently switched to active due to events like program errors. The other is by the use of dead time timers. A dead time timer delays the turn-on of one transistor in order to ensure that an adequate time (the dead time) passes after the other is turned off.

To disable simultaneous turn-on output signals, the INV04 bit in the INVC0 register should be set to 1. If outputs for any pair of phases (U and $\overline{\text{U}}$, V and $\overline{\text{V}}$, or W and $\overline{\text{W}}$) are simultaneously switched to an active state, every three-phase motor control output pin becomes high-impedance. Figure 16.15 shows an example of output waveform when simultaneous turn-on signal output is disabled.

To enable the dead time timer, the INV15 bit in the INVC1 register should be set to 0. The DTT register determines the dead time. Figure 16.16 shows the DTT register and Figure 16.17 shows an example of output waveform on using dead time timer.
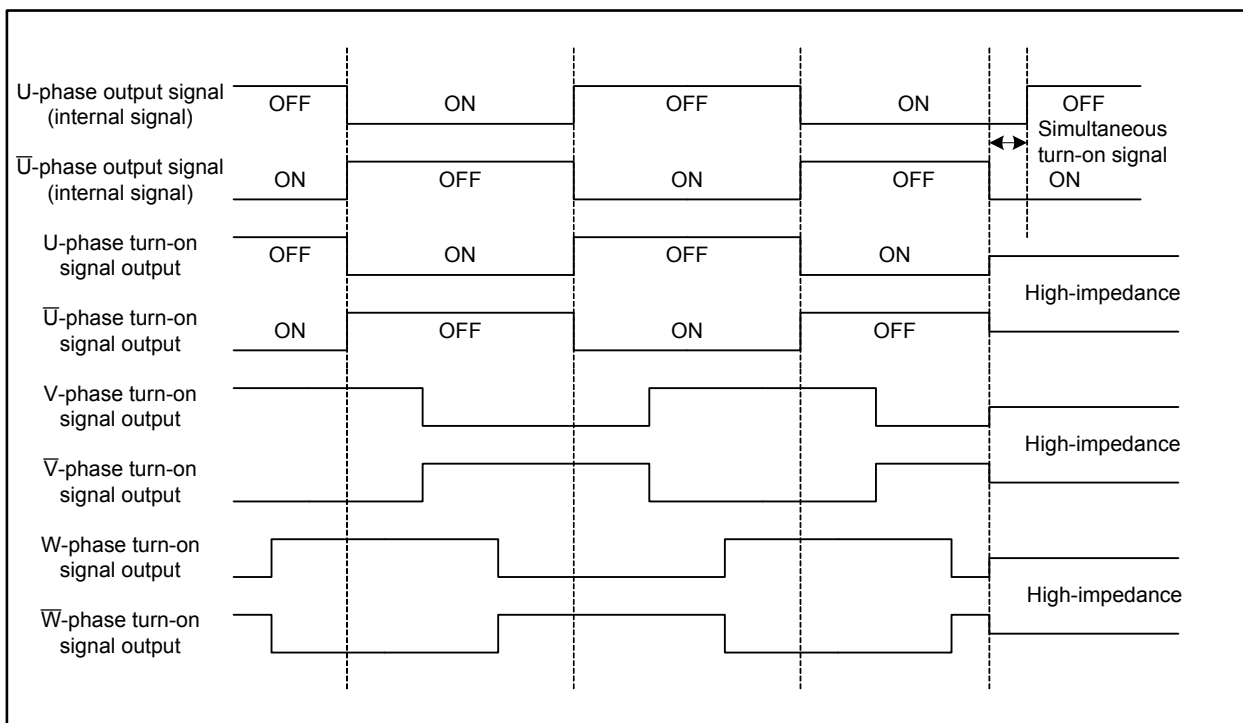

Figure 16.15 Output Waveform When Simultaneous Turn-on Signal Output is Disabled

Dead Time Timer [1, 2]

	Symbol	Address	Reset Value
b7 b0	DTT	030Ch	Undefined

Function	Setting Range	RW
The dead time timer is a one-shot timer that delays the timing for a turn-on signal to be switched to its active state preventing a simultaneous conduction of high-side and low-side transistors. The timer stops when counting a count source n times after a start trigger occurs (n = setting value) [3]	01h to FFh	WO

Notes:
1. Use the MOV instruction to set this register.
2. This register setting is enabled when the INV15 bit in the INVC1 register is 0 (enables dead time). No dead time can be set when the INV15 bit is 1 (disables dead time).
3. The trigger and count source should be selected using bits INV16 and INV12 in the INVC1 register, respectively.

Figure 16.16 DTT Register
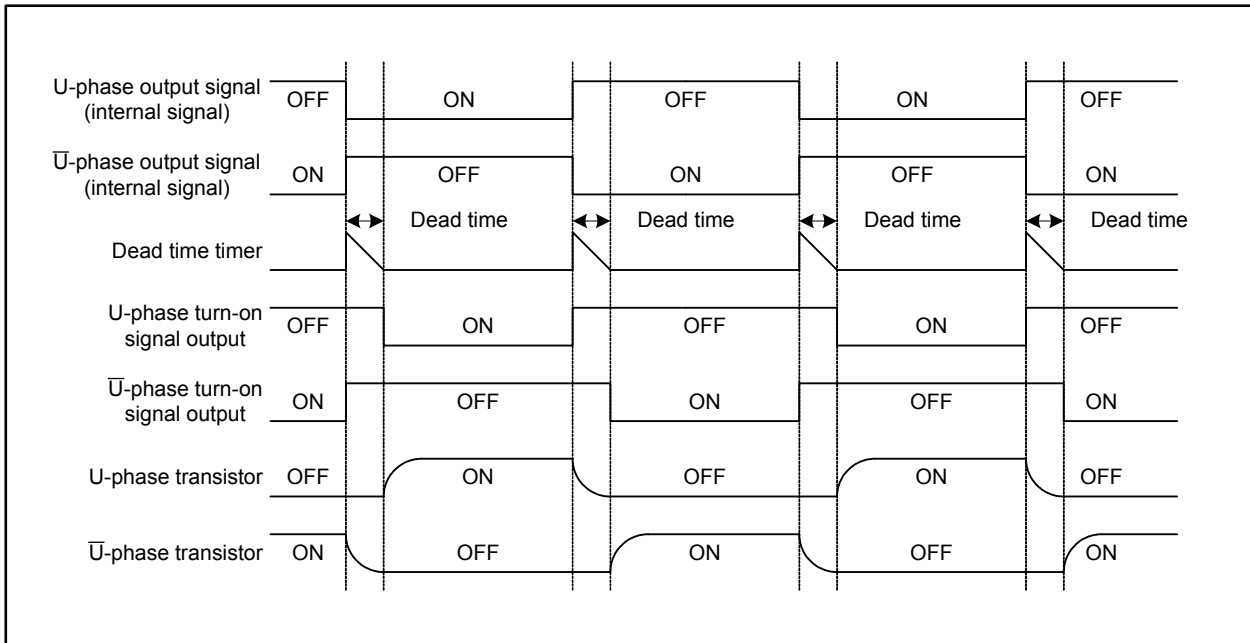

Figure 16.17 Output Waveform When Using Dead Time Timer

16.5 Three-phase Motor Control Timer Operation

Figures 16.18 and 16.19 show an operation example of triangular wave modulation and sawtooth wave modulation, respectively.

Figure 16.18 Triangular Wave Modulation Operation

This figure applies when INVC0 = 00XX11XXb (X varies depending on each system) and INVC1 = 010XXXX0b.
PWM output may vary as follows:

(A) When INV11 = 1 (three-phase mode 1)
   - INV01 = 0 and ICTB2 = 2h (timer B2 interrupt occurs every second time timer B2 underflows), or
     INV01 = 1, INV00 = 1, and ICTB2 = 1h (timer B2 interrupt occurs every time timer B2 underflows when the
     reload control signal for timer A1 is 1)
   - The setting of registers TA4 and TA41 are varied every time a timer B2 interrupt occurs,
     Default value: TA41 = a', TA4 = a
     On the first timer B2 interrupt: TA41 = b', TA4 = b; the second time: TA41 = c', TA4 = c
   - Default value of registers IDB0 and IDB1: DU0 = 1, DUB0 = 0, DU1 = 0, DUB1 = 1
     On the third time: DU0 = 1, DUB0 = 0, DU1 = 1, DUB1 = 0
 (B) When INV11 = 0 (three-phase mode 0)
   - INV01 = 0 and ICTB2 = 1h (timer B2 interrupt occurs every time timer B2 underflows)
   - TA4 register setting is varied every time a timer B2 interrupt occurs,
     Default value: TA4 = a'
     On the first timer B2 interrupt: TA4 = a; 2nd time: TA4 = b'; 3rd time: TA4 = b; 4th time: TA4 = c'; 5th time: TA4 = c
   - Default value of registers IDB0 and IDB1: DU0 = 1, DUB0 = 0, DU1 = 0, DUB1 = 1
     On the sixth time: DU0 = 1, DUB0 = 0, DU1 = 1, DUB1 = 0
Notes:
   1. Internal signal. Refer to the block diagram of three-phase motor control timers.
   2. Applicable when the INV11 bit in the INVC1 register is 1 (three-phase mode 1).

This figure applies when INVC0 = 01XX110Xb (X varies depending on each system) and INVC1 = 000XXX00b. This bit setting is applicable to turn-on control with a phase shift of 120 degrees.

PWM output may vary as follows:
    Default value of registers IDB0 and IDB1: DU0 = 0, DUB0 = 1, DU1 = 1, DUB1 = 1
    On the third timer B2 interrupt: DU0 = 1, DUB0 = 1, DU1 = 1, DUB1 = 1
    On the fifth timer B2 interrupt: DU0 = 1, DUB0 = 0, DU1 = 1, DUB1 = 1

Note:
    1.   Internal signal. Refer to the block diagram of three-phase motor control timers.

Figure 16.19 Sawtooth Wave Modulation Operation

16.6   Notes on Three-phase Motor Control Timers

16.6.1   Shutdown

- When a low signal is applied to the $\overline{\text{NMI}}$ pin with the following bit settings, pins TA1OUT, TA2OUT, and TA4OUT become high-impedance: the PM24 bit in the PM2 register is 1 (NMI enabled), the SDE bit in the IOBC register is 1 (shutdown enabled), the INV02 bit in the INVC0 register is 1 (three-phase motor control timers used), and the INV03 bit is 1 (three-phase motor control timer output enabled).

16.6.2   Register Setting

- Do not write to the TAi1 register before and after timer B2 underflows (i = 1, 2, 4). Before writing to the TAi1 register, read the TB2 register to verify that sufficient time remains until timer B2 underflows. Then, immediately write to the TAi1 register so no interrupt handling is performed during this write procedure. If the TB2 register indicates little time remains until the underflow, write to the TAi1 register after timer B2 underflows.

17. Serial Interface

The serial interface consists of five channels: UART0 to UART4.
Each channel has an exclusive timer to generate the transmit/receive clock and operates independently.
Figures 17.1 and 17.2 show block diagrams of UART0 to UART2 and UART3 and UART4, respectively.
UARTi supports the following modes:
- Synchronous serial interface mode (for UART0 to UART4)
- Asynchronous serial interface mode (UART mode) (for UART0 to UART4)
- Special mode 1 (I^{2}C mode) (for UART0 to UART2)
- Special mode 2 (for UART0 to UART2)

Figures 17.3 to 17.17 show registers associated with UARTi (i = 0 to 4).

Refer to the tables listing each mode for registers and pin settings.

1. Bits OER, FER, PER, and SUM become 0 when bits SMD2 to SMD0 in the UiMR register are set to 000b (serial interface disabled) or the RE bit in the UiC1 register is set to 0 (reception disabled). When bits OER, FER, and PER all become 0, the SUM bit also becomes 0. Bits FER and PER become 0 when the lower byte in the UiRB register is read.
2. When bits SMD2 to SMD0 are 001b (synchronous serial interface mode) or 010b (I^2C mode), these error flags are disabled and read as an undefined value.

Figure 17.17 Registers U3RB and U4RB

17.1   Synchronous Serial Interface Mode

The synchronous serial interface mode allows data transmission/reception synchronized with the transmit/receive clock. Table 17.2 lists specifications of synchronous serial interface mode.

Table 17.2   Synchronous Serial Interface Mode Specifications

Item	Specification
Data format	8-bit character length
Transmit/receive clock	• The CKDIR bit in the UiMR register is 0 (internal clock) (i = 0 to 4): $$\frac{fx}{2(m+1)} \quad fx = \text{f1, f8, f2n; } m\text{: UiBRG register setting value, 00h to FFh}$$ • The CKDIR bit is 1 (external clock): input to the CLKi pin
Transmit/receive control	CTS function enabled, RTS function enabled, or CTS/RTS function disabled
Transmit start conditions	The conditions for starting data transmission are as follows [1]: • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register) • Input level at the $\overline{\text{CTSi}}$ pin is low when the CTS function is selected
Receive start conditions	The conditions for starting data reception are as follows [1]: • The RE bit in the UiC1 register is 1 (reception enabled) • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register) • Input level at the $\overline{\text{CTSi}}$ pin is low when the CTS function is selected

Interrupt request generating timing	In transmit interrupt, one of the following conditions can be selected by setting the UiIRS bit in registers U0C1 to U2C1 and U34CON:
	• The UiIRS bit is 0 (transmit buffer is empty):
	  when data is transferred from the UiTB register to the UARTi transmit register (when the transmission has started)
	• The UiIRS bit is 1 (transmission is completed):
	  when data transmission from the UARTi transmit register is completed
	In receive interrupt,
	• When data is transferred from the UARTi receive register to the UiRB register (when the reception is completed)

Error detection	Overrun error [2] This error occurs when the seventh bit of the next data is received before the UiRB register is read

Other functions	• CLK polarity
	  Rising or falling edge of the transmit/receive clock for output and input of transmit/receive data
	• Bit order selection
	  LSB first or MSB first
	• Continuous receive mode
	  Data reception is enabled by a read access to the UiRB register
	• Serial data logic inversion (UART0 to UART2)
	  This function logically inverses transmit/receive data

Notes:
1. When selecting an external clock, the following preconditions should be met:
    • The CLKi pin is held high when the CKPOL bit in the UiC0 register is set to 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge).
    • The CLKi pin is held low when the CKPOL bit is set to 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge).
2. The UiRB register is undefined when an overrun error occurs. The IR bit in the SiRIC register does not change to 1 (interrupt requested).

Tables 17.3 and 17.4 list register settings. When UARTi operating mode is selected, a high is output at the TXDi pin until transmission starts (the TXDi pin is high-impedance when the N-channel open drain output is selected) (i = 0 to 4).

Figures 17.18 and 17.19 show examples of transmit and receive operations in synchronous serial interface mode, respectively.

Table 17.3   Register Settings in Synchronous Serial Interface Mode (for UART0 to UART2)

Register	Bits	Function
UiMR	7 to 4	Set the bits to 0000b
	CKDIR	Select either an internal clock or external clock
	SMD2 to SMD0	Set the bits to 001b
UiC0	UFORM	Select either LSB first or MSB first
	CKPOL	Select a transmit/receive clock polarity
	NCH	Select an output mode of the TXDi pin
	CRD	Select CTS function enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	7	Set the bit to 0
	UiLCH	Set the bit to 1 to use logic inversion
	UiRRM	Set the bit to 1 to use continuous receive mode
	UiIRS	Select a source for the UARTi transmit interrupt
	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission/reception
UiSMR	7 to 0	Set the bits to 00h
UiSMR2	7 to 0	Set the bits to 00h
UiSMR3	7 to 4	Set the bits to 0000b
	NODC	Select a clock output mode
	2 to 0	Set the bits to 000b
UiSMR4	7 to 0	Set the bits to 00h
UiBRG	7 to 0	Set the bit rate
UiTB	7 to 0	Set the data to be transmitted
UiRB	OER	Overrun error flag
	7 to 0	Received data is read

i = 0 to 2

Table 17.4   Register Settings in Synchronous Serial Interface Mode (for UART3 and UART4)

Register	Bits	Function
UiMR	7 to 4	Set the bits to 0000b
	CKDIR	Select an internal clock or external clock
	SMD2 to SMD0	Set the bits to 001b
UiC0	UFORM	Select either LSB first or MSB first
	CKPOL	Select a transmit/receive clock polarity
	5	Set the bit to 0
	CRD	Select CTS function enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission/reception
U34CON	UiRRM	Set the bit to 1 to use continuous receive mode
	UiIRS	Select an interrupt source for UARTi transmit
IFS0	IFS05 and IFS04	Select input pins for CLK4, RXD4, and $\overline{\text{CTS4}}$
	IFS03 and IFS02	Select input pins for CLK3, RXD3, and $\overline{\text{CTS3}}$
UiBRG	7 to 0	Set the bit rate
UiTB	7 to 0	Set the data to be transmitted
UiRB	OER	Overrun error flag
	7 to 0	Received data can be read

i = 3, 4
Figure 17.18 Transmit Operation in Synchronous Serial Interface Mode

Receive timing (when selecting an external clock)
Figure 17.19 Receive Operation in Synchronous Serial Interface Mode

17.1.1   Reset Procedure on Transmit/Receive Error

When a transmit/receive error occurs in synchronous serial interface mode, follow the procedures below to perform a reset:

A. Reset procedure for the UiRB register (i = 0 to 4)

(1) Set the RE bit in the UiC1 register to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 to 001b (synchronous serial interface mode).
(4) Set the RE bit in the UiC1 register to 1 (reception enabled).

B. Reset procedure for the UiTB register

(1) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(2) Set bits SMD2 to SMD0 to 001b (synchronous serial interface mode).
(3) Irrespective of its status, set the TE bit in the UiC1 register to 1 (transmission enabled).

17.1.2   CLK Polarity

As shown in Figure 17.20, the polarity of the transmit/receive clock is selected using the CKPOL bit in the UiC0 register (i = 0 to 4).

(A) When the CKPOL bit in the UiC0 register is 0 (output transmit data on the falling edge of the transmit/receive clock and input receive data on the rising edge)

Notes:
1. The CLKi pin is held high when no data is transmitted/received.
2. This figure applies under the following conditions:
    - The UFORM bit in the UiC0 register is 0 (LSB first).
    - The UiLCH bit in the UiC1 register is 0 (data is not logic inverted).

(B) When the CKPOL bit in the UiC0 register is 1 (output transmit data on the rising edge of the transmit/receive clock and input receive data on the falling edge)

Notes:
3. The CLKi pin is held low when no data is transmitted/received.
4. This figure applies under the following conditions:
    -The UFORM bit in the UiC0 register is 0 (LSB first).
    -The UiLCH bit in the UiC1 register is 0 (data is not logic inverted).

Figure 17.20 Transmit/Receive Clock Polarity (i = 0 to 4)

17.1.3   LSB First and MSB First Selection

As shown in Figure 17.21, the bit order is selected by setting the UFORM bit in the UiC0 register (i = 0 to 4).

(A)   When the UFORM bit in the UiC0 register is 0 (LSB first)

CLKi

TXDi   D0   D1   D2   D3   D4   D5   D6   D7

RXDi   D0   D1   D2   D3   D4   D5   D6   D7

Note:
1. This figure applies under the following conditions:
- The CKPOL bit in the UiC0 register is 0 (output transmit data on the falling edge of the transmit/
receive clock and input receive data on the rising edge).
- The UiLCH bit in the UiC1 register is 0 (data is not logic inverted).

(B)   When the UFORM bit in the UiC0 register is 1 (MSB first)

CLKi

TXDi   D7   D6   D5   D4   D3   D2   D1   D0

RXDi   D7   D6   D5   D4   D3   D2   D1   D0

Note:
2. This figure applies under the following conditions:
- The CKPOL bit in the UiC0 register is 0 (output transmit data on the falling edge of the transmit/
receive clock and input receive data on the rising edge).
- The UiLCH bit in the UiC1 register is 0 (data is not logic inverted).

Figure 17.21 Bit Order (i = 0 to 4)

17.1.4   Continuous Receive Mode

In continuous receive mode, data reception is automatically enabled by a read access to the receive buffer register without writing dummy data to the transmit buffer register. To start data reception, however, dummy data is required to read the receive buffer register.

When the UiRRM bit in registers U0C1 to U2C1 and the U34CON register is set to 1 (continuous receive mode enabled), the TI bit in the UiC1 register becomes 0 (data held in the UiTB register) by a read access to the UiRB register (i = 0 to 4). In this UiRRM bit setting, no dummy data should be written to the UiTB register.

17.1.5   Serial Data Logic Inversion

When the UiLCH bit in the UiC1 register is 1 (data is logic inverted), the logical value written in the UiTB register is inverted before being transmitted (i = 0 to 2). The UiRB register is read as logic-inverted receive data. Figure 17.22 shows the logic inversion of serial data.

(A)   When the UiLCH bit in the UiC1 register is 0 (data is not logic inverted)

CLKi

TXDi   D0   D1   D2   D3   D4   D5   D6   D7

(B)   When the UiLCH bit in the UiC1 register is 1 (data is logic inverted)

CLKi

TXDi $\overline{D0}$ $\overline{D1}$ $\overline{D2}$ $\overline{D3}$ $\overline{D4}$ $\overline{D5}$ $\overline{D6}$ $\overline{D7}$

Note:
1. This figure applies under the following conditions:
   - The CKPOL bit in the UiC0 register is 0 (output transmit data on the falling edge of the transmit/receive clock and input receive data on the rising edge).
   - The UFORM bit is 0 (LSB first).

Figure 17.22 Serial Data Logic Inversion (i = 0 to 2)

17.1.6   CTS/RTS Function

CTS function controls data transmission using the $\overline{\text{CTSi}}$/$\overline{\text{RTSi}}$ pin (i = 0 to 4). When an input level at the pin becomes low, data transmission starts. If the input level changes to high during transmission, the transmission of the next data is stopped.

In synchronous serial interface mode, the transmitter is required to operate even during the receive operation. If CTS function is enabled, the input level at the $\overline{\text{CTSi}}$/$\overline{\text{RTSi}}$ pin should be low to start data reception as well.

RTS function indicates receiver status using the $\overline{\text{CTSi}}$/$\overline{\text{RTSi}}$ pin. When data reception is ready, the output level at the pin becomes low. It becomes high on the first falling edge of the CLKi pin.

17.2   Asynchronous Serial Interface Mode (UART Mode)

The UART mode enables data transmission/reception synchronized with an internal clock generated by a trigger on the falling edge of the start bit. Table 17.5 lists specifications of UART mode.

Table 17.5   UART Mode Specifications

Item	Specification
Data format	• Start bit: 1-bit • Data bit (data character): 7-bit, 8-bit, or 9-bit • Parity bit: odd, even, or none • Stop bit: 1-bit or 2-bit
Transmit/receive clock	• The CKDIR bit in the UiMR register is 0 (internal clock) (i = 0 to 4): $$\frac{fx}{16(m+1)} \qquad fx = \text{f1, f8, f2n; } m: \text{UiBRG register setting value, 00h to FFh}$$ • The CKDIR bit is 1 (external clock) $$\frac{fEXT}{16(m+1)} \qquad fEXT: \text{Clock applied to the CLKi pin}$$
Transmit/receive control	CTS function enabled, RTS function enabled, or CTS/RTS function disabled
Transmit start conditions	The conditions for starting data transmission are as follows: • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register) • Input level at the $\overline{\text{CTSi}}$ pin is low when CTS function is selected
Receive start conditions	The conditions for starting data reception are as follows: • The RE bit in the UiC1 register is 1 (reception enabled) • The start bit is detected

Interrupt request generating timing	In transmit interrupt, one of the following conditions can be selected by setting the UiIRS bit in registers U0C1 to U2C1 and the U34CON register:
	• The UiIRS bit is 0 (transmit buffer is empty):
	  when data is transferred from the UiTB register to the UARTi transmit register (when the transmission has started)
	• The UiIRS bit is 1 (transmission is completed):
	  when data transmission from the UARTi transmit register is completed
	In receive interrupt,
	• When data is transferred from the UARTi receive register to the UiRB register (when reception is completed)

Error detection	• Overrun error [1]
	  This error occurs when 1 bit prior to the stop bit (when 1 stop bit length is selected) or the first stop bit (when 2 stop bit length is selected) of the next data is received before the UiRB register is read
	• Framing error
	  This error occurs when the required number of stop bits is not detected
	• Parity error
	  This error occurs when an even number of 1's in parity and character bits is detected while the odd number is set, or vice versa. The parity should be enabled
	• Error sum flag
	  This flag becomes 1 when any of overrun error, framing error, or parity error occurs

Other functions	• Bit order selection
	  LSB first or MSB first
	• Serial data logic inversion
	  This function logically inverses transmit/receive data. The start bit and stop bit are not inverted
	• TXD/RXD I/O polarity switching
	  The output level from the TXD pin and the input level to the RXD pin are inverted. All I/O levels are inverted

Note:
1. The UiRB register is undefined when an overrun error occurs. The IR bit in the SiRIC register does not change to 1 (interrupt requested).

Tables 17.6 and 17.7 list register settings. When UARTi operating mode is selected, a high is output at the TXDi pin until transmission starts (the TXDi pin is high-impedance when the N-channel open drain output is selected) (i = 0 to 4).
Figures 17.23 and 17.24 show examples of transmit operations in UART mode. Figure 17.25 shows an example of receive operation.

Table 17.6   Register Settings in UART Mode (UART0 to UART2)

Register	Bits	Function
UiMR	IOPOL	Select I/O polarity of pins TXD and RXD
	PRY and PRYE	Select parity enabled or disabled, and odd or even
	STPS	Select a stop bit length
	CKDIR	Select an internal clock or external clock
	SMD2 to SMD0	Set the bits to 100b in 7-bit character length
		Set the bits to 101b in 8-bit character length
		Set the bits to 110b in 9-bit character length
UiC0	UFORM	Select LSB first or MSB first in 8-bit character length. Set the bit to 0 in 7-bit or 9-bit character length
	CKPOL	Set the bit to 0
	NCH	Select an output mode for the TXDi pin
	CRD	Select CTS function enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	7	Set the bit to 0
	UiLCH	Set the bit to 1 to use logic inversion
	UiRRM	Set the bit to 0
	UiIRS	Select an interrupt source for UARTi transmission
	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission
UiSMR	7 to 0	Set the bits to 00h
UiSMR2	7 to 0	Set the bits to 00h
UiSMR3	7 to 0	Set the bits to 00h
UiSMR4	7 to 0	Set the bits to 00h
UiBRG	7 to 0	Set the bit rate
UiTB	8 to 0	Set the data to be transmitted [1]
UiRB	OER, FER, PER, and SUM	Error flag
	8 to 0	Received data is read [1]

 i = 0 to 2

Note:
    1.   The bits used are as follows: 7-bit character length: bits 6 to 0
                                    8-bit character length: bits 7 to 0
                                    9-bit character length: bits 8 to 0

Table 17.7   Register Settings in UART Mode (UART3, UART4)

Register	Bits	Function
UiMR	PRY and PRYE	Select parity enabled or disabled, and odd or even
	STPS	Select a stop bit length
	CKDIR	Select an internal clock or external clock
	SMD2 to SMD0	Set the bits to 100b in 7-bit character length
		Set the bits to 101b in 8-bit character length
		Set the bits to 110b in 9-bit character length
UiC0	UFORM	Select LSB first or MSB first in 8-bit character length. Set the bit to 0 in 7-bit or 9-bit character length
	CKPOL	Set the bit to 0
	5	Set the bit to 0
	CRD	Select CTS function enabled or disabled
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission
U34CON	UiRRM	Set the bit to 0
	UiIRS	Select an interrupt source for UARTi transmission
UiBRG	7 to 0	Set the bit rate
IFS0	IFS05 and IFS04	Select input pins for CLK4, RXD4, and $\overline{CTS4}$
	IFS03 and IFS02	Select input pins for CLK3, RXD3, and $\overline{CTS3}$
UiTB	8 to 0	Set the data to be transmitted [1]
UiRB	OER, FER, PER, and SUM	Error flag
	8 to 0	Received data is read [1]

i = 3, 4

Note:
   1.   The bits used are as follows: 7-bit character length: bits 6 to 0
                                                      8-bit character length: bits 7 to 0
                                                      9-bit character length: bits 8 to 0

Figure 17.23 Transmit Operation in UART Mode (1/2) (i = 0 to 4)

This figure applies under the following conditions:
   - The PRYE bit in the UiMR register is 0 (parity disabled).
   - The STPS bit in the UiMR register is 0 (1 stop bit).

Figure 17.25 Receive Operation in UART Mode (i = 0 to 4)

17.2.1   Bit Rate

In UART mode, the bit rate is a clock frequency which is divided by a setting value of the UiBRG register and again divided by 16 (i = 0 to 4). Table 17.8 lists an example of bit rate setting.

Table 17.8   Bit Rate Setting

Bit Rate (bps)	Count Source of BRG	Peripheral Clock: 30 MHz		Peripheral Clock: 32 MHz	
		Setting value of BRG: n	Actual bit rate (bps)	Setting value of BRG: n	Actual bit rate (bps)
1200	f8	194 (C2h)	1202	207 (CHh)	1202
2400	f8	97 (61h)	2392	103 (67h)	2404
4800	f8	48 (30h)	4783	51 (33h)	4808
9600	f1	194 (C2h)	9615	207 (CFh)	9615
14400	f1	129 (81h)	14423	138 (8Ah)	14388
19200	f1	97 (61h)	19133	103 (67h)	19231
28800	f1	64 (40h)	28846	68 (44h)	28986
31250	f1	59 (3Bh)	31250	63 (3Fh)	31250
38400	f1	48 (30h)	38265	51 (33h)	38462
51200	f1	36 (24h)	50676	38 (26h)	51282

17.2.2   Reset Procedure on Transmit/Receive Error

When a transmit/receive error occurs in UART mode, follow the procedure below to perform a reset:

A. Reset procedure for the UiRB register (i = 0 to 4)

(1) Set the RE bit in the UiC1 register to 0 (reception disabled).
(2) Set the RE bit in the UiC1 register to 1 (reception enabled).

B. Reset procedure for the UiTB register

(1) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(2) Set again bits SMD2 to SMD0 to either of 001b, 101b, or 110b.
(3) Irrespective of its status, set the TE bit in the UiC1 register to 1 (transmission enabled).

17.2.3   LSB First and MSB First Selection

As shown in Figure 17.26, the bit order is selected by setting the UFORM bit in the UiC0 register (i = 0 to 4). This function is available when the character length is 8-bit.
Figure 17.26 Bit Order (i = 0 to 4)

17.2.4   Serial Data Logic Inversion

When the UiLCH bit in the UiC1 register is 1 (data is logic inverted), the logical value written in the UiTB register is inverted before being transmitted (i = 0 to 2). The UiRB register is read as logic-inverted receive data. The parity bit is not inverted. Figure 17.27 shows the logic inversion of serial data.
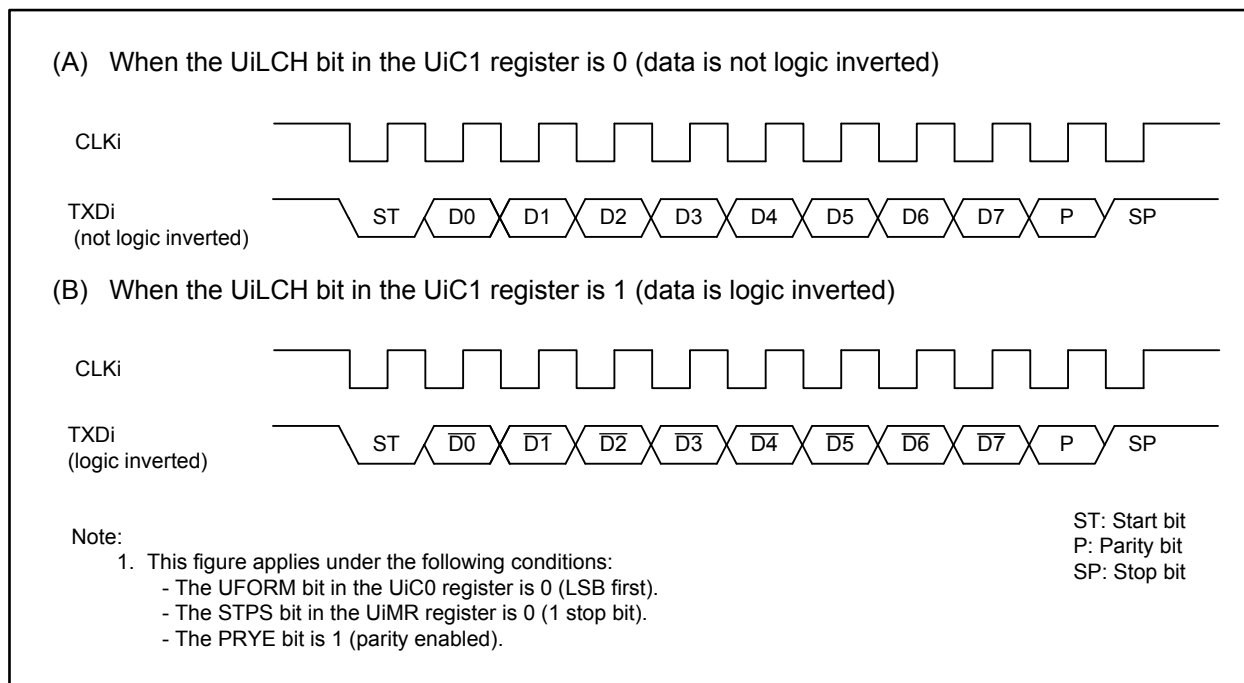

Figure 17.27 Serial Data Logic Inversion (i = 0 to 2)

17.2.5   TXD and RXD I/O Polarity Inversion

The output level at the TXD pin and the input level at the RXD pin are inverted by this function. All I/O data levels, including the start bit, stop bit, and parity bit are inverted by setting the IOPOL bit in the UiMR register to 1 (inverted) (i = 0 to 2). Figure 17.28 shows TXD and RXD I/O polarity inversion.
Figure 17.28 TXD and RXD I/O Polarity Inversion (i = 0 to 2)

17.2.6   CTS/RTS Function

CTS function controls data transmission using the $\overline{\text{CTSi}}$/$\overline{\text{RTSi}}$ pin (i = 0 to 4). When an input level at the pin becomes low, data transmission starts. If the input level changes to high during transmit operation, transmission of the next data is stopped.

RTS function indicates receiver status using the $\overline{\text{CTSi}}$/$\overline{\text{RTSi}}$ pin. When the MCU is ready to receive data, the output level at the pin becomes low. It becomes high on the first falling edge of the CLKi pin.

17.3   Special Mode 1 (I2C Mode)

This mode uses an I2C-typed interface for communication. Table 17.9 lists specifications of the I2C mode.

Table 17.9   I2C Mode Specifications

Item	Specification
Data format	8-bit character length
Transmit/receive clock	In master mode • The CKDIR bit in the UiMR register is 0 (internal clock) (i = 0 to 2): $$\frac{fx}{2(m+1)} \qquad fx = \text{f1, f8, f2n}$$ m: UiBRG register setting value, 00h to FFh In slave mode • The CKDIR bit is 1 (external clock): input to the SCLi pin
Transmit start conditions	The conditions for starting data transmission are as follows [1]: • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register)
Receive start conditions	The conditions for starting data reception are as follows [1]: • The RE bit in the UiC1 register is 1 (reception enabled) • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register)
Interrupt request generating timing	When any of the following is detected: START condition, STOP condition, NACK (not-acknowledge), or ACK (acknowledge)
Error detection	Overrun error [2] This error occurs when the eighth bit of the next data is received before the UiRB register is read

Other functions	• Arbitration lost
	  Update timing of the ABT bit in the UiRB register can be selected
	• SDAi digital delay
	  No digital delay or two to eight cycles of digital delay of UiBRG count source
	• Clock phase setting
	  Clock delayed or no clock delay

Notes:
1.   When an external clock is selected, the conditions should be met while the external clock signal is held high.
2.   The UiRB register is undefined when an overrun error occurs. The IR bit in the SiRIC register does not change to 1 (interrupt requested).

Table 17.10 lists register settings in I2C mode, and Tables 17.11 and 17.12 list I2C mode functions. Figure 17.29 shows a block diagram of I2C mode, and Figure 17.30 shows timings for the transfer to the UiRB register and the interrupt (i = 0 to 2).

As shown in Tables 17.11 and 17.12, UARTi enters this mode when bits SMD2 to SMD0 in the UiMR register are set to 010b, and the IICM bit in the UiSMR register is set to 1 (i = 0 to 2). Since a transmit signal at the SDAi pin is output via the delay circuit, it changes after the SCLi pin is stably held low.
Figure 17.29 I²C Mode Block Diagram (i = 0 to 2)

Table 17.10 Register Settings in I^{2}C Mode (i = 0 to 2)

Register	Bits	Function	
		Master	Slave
UiMR	IOPOL	Set the bit to 0	
	CKDIR	Set the bit to 0	Set the bit to 1
	SMD2 to SMD0	Set the bit to 010b	
UiC0	7 to 4	Set the bits to 1011b	
	TXEPT	Transmit register empty flag	
	2	Set the bit to 0	
	CLK1 and CLK0	Select a count source for the UiBRG register	Disabled
UiC1	7 to 5	Set the bits to 000b	
	UiIRS	Set the bit to 1	
	RI	Receive complete flag	
	RE	Set the bit to 1 to enable data reception	
	TI	Transmit buffer empty flag	
	TE	Set the bit to 1 to enable data transmission/reception	
UiSMR	7 to 3	Set the bits to 00000b	
	BBS	Bus busy flag	
	ABC	Select an arbitration lost detection timing	Disabled
	IICM	Set the bit to 1	
UiSMR2	7	Set the bit to 0	
	SDHI	Set the bit to 1 to disable the SDA output	
	SWC2	Set the bit to 1 to hold the SCL output at a forcible low	
	STC	Set the bit to 0	Set the bit to 1 to reset UARTi by detecting the START condition
	ALS	Set the bit to 1 to stop the output at the SDAi pin to detect an arbitration lost	Set the bit to 0
	SWC	Set the bit to 1 to hold a low output at the SCLi pin after receiving the eighth bit of the clock	
	CSC	Set the bit to 1 to enable clock synchronization	Set the bit to 0
	IICM2	Refer to Tables 17.11 and 17.12	
UiSMR3	DL2 to DL0	Set the digital delay value of SDAi	
	4 to 2	Set the bit to 000b	
	CKPH	Refer to Tables 17.11 and 17.12	
	SSE	Set the bit to 0	
UiSMR4	SWC9	Set the bit to 0	Set the bit to 1 to hold a low output at the SCLi pin after receiving the ninth bit of the clock
	SCLHI	Set the bit to 1 to stop the SCL output to detect STOP condition	Set the bit to 0
	ACKC	Set the bit to 1 for ACK data output	
	ACKD	Select ACK or NACK	
	STSPSEL	Set the bit to 1 when any condition is output	Set the bit to 0
	STPREQ	Set the bit to 1 to generate a STOP condition	Set the bit to 0
	RSTAREQ	Set the bit to 1 to generate a repeated START condition	Set the bit to 0
	STAREQ	Set the bit to 1 to generate a START condition	Set the bit to 0
UiBRG	7 to 0	Set the bit rate	Disabled
UiTB	8	Set the bit to 1 when transmitting. Set the bit to the value of the ACK bit when receiving	
	7 to 0	Set the data to be transmitted when transmitting. Set the register to FFh when receiving	
UiRB	OER	Overrun error flag	
	ABT	Arbitration lost detection flag	Disabled
	8	D0 is loaded immediately after a receive interrupt occurs. ACK or NACK is loaded after a transmit interrupt occurs	
	7 to 0	D7 to D1 are read immediately after a receive interrupt occurs. D7 to D0 are read after a transmit interrupt occurs	

Table 17.11   I2C Mode Functions (i = 0 to 2) (1/2)

Function	Synchronous Serial Interface Mode (SMD2 to SMD0 are 001b, IICM is 0)	I2C Mode (SMD2 to SMD0 are 010b, IICM is 1)			
		IICM2 is 0 (ACK/NACK interrupt)		IICM2 is 1 (Transmit/receive interrupt)	
		CKPH is 0 (No clock delay)	CKPH is 1 (Clock delayed)	CKPH is 0 (No clock delay)	CKPH is 1 (Clock delayed)
Source of software interrupt numbers 39 to 41 [1] (refer to Figure 17.30)	—	START condition or STOP condition detection (refer to Table 17.13)			
Source of software interrupt numbers 17, 19, and 33 [1] (refer to Figure 17.30)	UARTi transmission: Transmission started or completed (selected using the UiIRS register)	NACK detection: Rising edge of the ninth bit of SCLi		UARTi transmission: Rising edge of the ninth bit of SCLi	UARTi transmission: Falling edge of the ninth bit of SCLi
Source of software interrupt numbers 18, 20, and 34 [1] (refer to Figure 17.30)	UARTi reception: Receiving at eighth bit CKPOL is 0 (rising edge) CKPOL is 1 (falling edge)	ACK detection: Rising edge of the ninth bit of SCLi		UARTi reception: Falling edge of the eighth bit of SCLi	
Data transfer timing from the UARTi receive register to the UiRB register	CKPOL is 0 (rising edge) CKPOL is 1 (falling edge)	Rising edge of the ninth bit of SCLi	Falling edge of the eighth bit of SCLi	Falling edge of the eighth bit and rising edge of the ninth bit of SCLi	
UARTi transmit output delay	No delay	Delayed			
Pins P6_3, P6_7, P7_0	TXDi output	SDAi I/O			
Pins P6_2, P6_6, P7_1	RXDi input	SCLi I/O			
Pins P6_1, P6_5, P7_2	Select CLKi input or output	— (Not used in I2C mode)			

Note:
1. Steps to change an interrupt source are as follows:
    (1) Disable the interrupt of the corresponding software interrupt number.
    (2) Change the source of interrupt.
    (3) Set the IR bit of the corresponding software interrupt number to 0 (no interrupt requested).
    (4) Set bits ILVL2 to ILVL0 of the corresponding software interrupt number.

Table 17.12   I2C Mode Functions (i = 0 to 2) (2/2)

Function	Synchronous Serial Interface Mode (SMD2 to SMD0 are 001b, IICM is 0)	I2C Mode (SMD2 to SMD0 are 010b, IICM is 1)			
		IICM2 is 0 (ACK/NACK interrupt)		IICM2 is 1 (Transmit/receive interrupt)	
		CKPH is 0 (No clock delay)	CKPH is 1 (Clock delayed)	CKPH is 0 (No clock delay)	CKPH is 1 (Clock delayed)
Read level at pins RXDi and SCLi	Readable irrespective of the port direction bit				
Default output value at the SDAi pin	—	High (Value set in the port Pi register if the I/O port is selected by output function select registers (i = 0 to 7))			
SCLi default and end values	—	High	Low	High	Low
DMA source (refer to Figure 17.30)	UARTi reception	ACK detection		UARTi reception: Falling edge of the eighth bit of SCLi	
Store received data	The first to eighth bits of received data are stored into bits 0 to 7 in the UiRB register	The first to eighth bits of received data are stored into bits 7 to 0 in the UiRB register		The first to seventh bits of received data are stored into bits 6 to 0 in the UiRB register and the eighth bit is stored into bit 8	Same as on the left column on the first data storing. [1] The first to eighth bits of received data are stored into 7 to 0 bits in the UiRB register and the ninth bit is stored into bit 8 on the second data storing [2]
Read received data	The UiRB register status is read as it is			Bits 6 to 0 in the UiRB register are read as bits 7 to 1 and bit 8 is read as bit 0	Same as on the left column on the first read. [1] The UiRB register status is read as it is on the second read [2]

Notes:
1. The first data transfer to the UiRB register starts on the rising edge of the eighth bit of SCLi.
2. The second data transfer to the UiRB register starts on the rising edge of the ninth bit of SCLi.
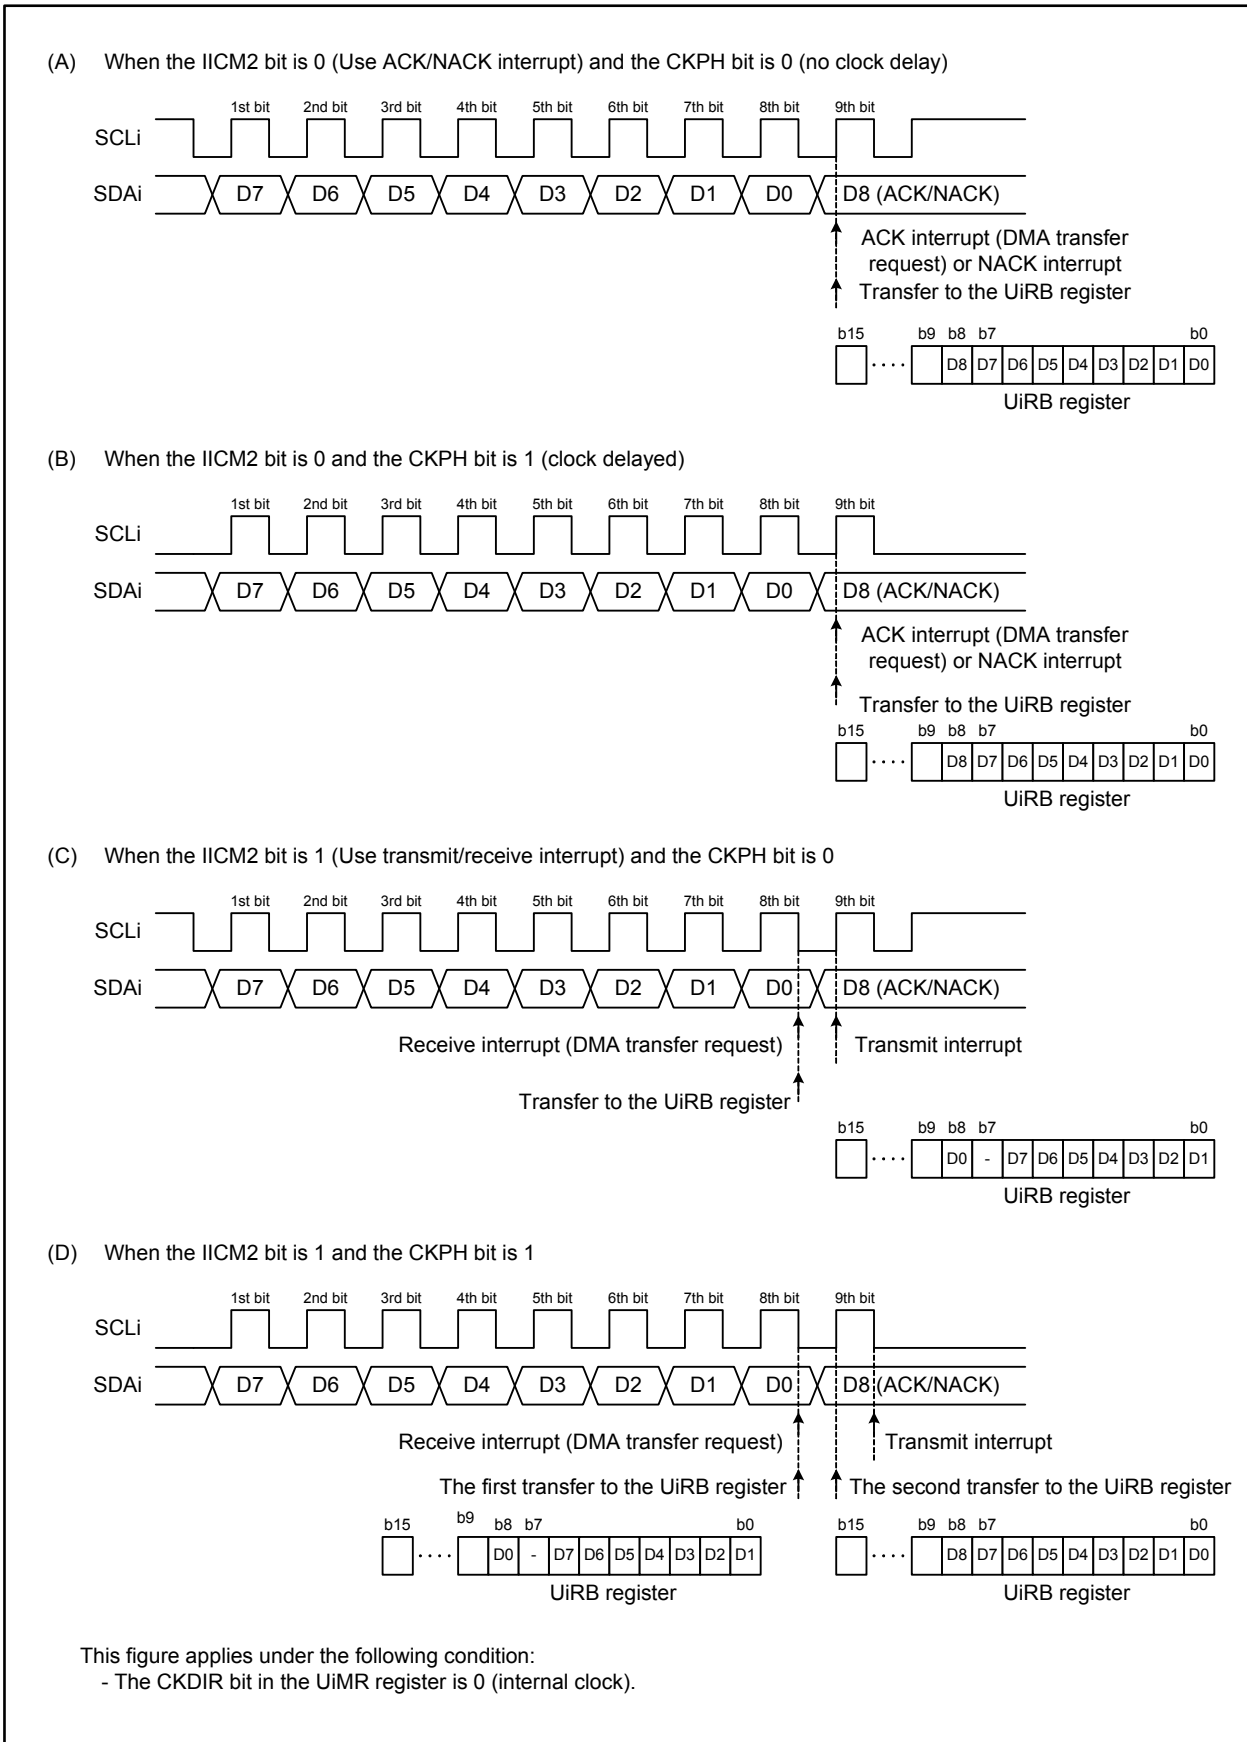

Figure 17.30 Timings for the Transfer and Interrupt to the UiRB Register (i = 0 to 2)

17.3.1   START Condition and STOP Condition Detection

The START condition and STOP condition are detected by their respective detectors.

The START condition detection interrupt request is generated by a high-to-low transition at the SDAi pin while the SCLi pin is held high (i = 0 to 2). The STOP condition detection interrupt request is generated by a low-to-high transition at the SDAi pin while the SCLi pin is held high.

The START condition detection interrupt shares interrupt control registers and vectors with the STOP condition detection interrupt. The BBS bit in the UiSMR register determines which interrupt is requested.

To detect a START condition or STOP condition, both set-up and hold times require at least six cycles of the peripheral clock (f1) as shown in Figure 17.31. To meet the condition for the Fast-mode specification, f1 must be at least 10 MHz.
Figure 17.31 START Condition and STOP Condition Detection Timing (i = 0 to 2)

17.3.2   START Condition and STOP Condition Generation

The START condition, repeated START condition, and STOP condition are generated by bits STAREQ, RSTAREQ, and STPREQ in the UiSMR4 register, respectively (i = 0 to 2). To output a START condition, set the STSPSEL bit in the UiSMR4 register to 1 (select START condition/STOP condition generation circuit) after setting the STAREQ bit to 1 (start). To output a repeated START condition or STOP condition, set the STSPSEL bit to 1 after setting RSTAREQ bit or STPREQ bit to 1, respectively.

Table 17.13 and Figure 17.32 show the functions of the STSPSEL bit.

Table 17.13   STSPSEL Bit Functions

Function	STSPSEL is 0	STSPSEL is 1
START condition and STOP condition generation	Output is provided by the program with port (no auto generation by hardware)	START condition or STOP condition is output according to the STAREQ, RSTAREQ, or STPREQ bit
START condition and STOP condition interrupt request generating timing	When START condition or STOP condition is detected	When START condition or STOP condition generation is completed
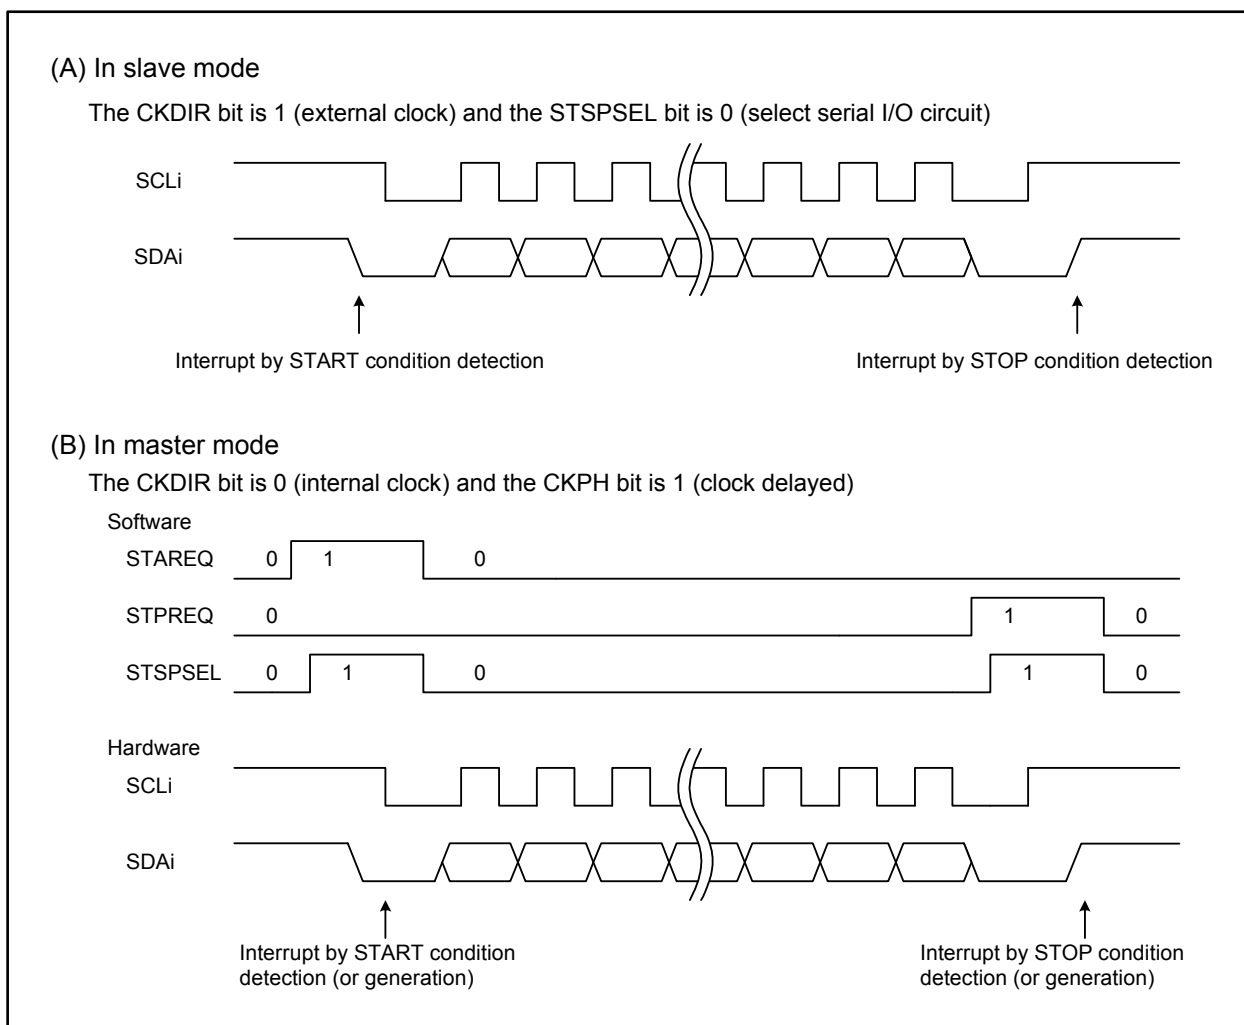

Figure 17.32 STSPSEL Bit Functions (i = 0 to 2)

17.3.3   Arbitration

On the rising edge of the SCLi, the MCU compares the transmit data with the data input from the SDAi pin. If no match is found, the MCU performs arbitration by stopping the SDAi output.

The update timing for the ABT bit in the UiRB register is selected by setting the ABC bit in the UiSMR register (i = 0 to 2).

When the ABC bit is 0 (update every bit), the ABT bit becomes 1 (detected (lose)) as soon as a data discrepancy is detected. If not detected, the ABT bit becomes 0 (not detected (win)). When the ABC bit is 1 (update every byte), the ABT bit becomes 1 on the falling edge of the eighth bit of the SCLi if any discrepancy is detected. In this ABC bit setting, set the ABT bit to 0 to start the next 1-byte transfer.

When the ALS bit in the UiSMR2 register is 1 (stop the SDAi output), the SDAi pin becomes high-impedance as the ABT bit becomes 1 when an arbitration lost occurs.

17.3.4   SCL Control and Clock Synchronization

Data transmission/reception in I2C mode uses the transmit/receive clock as shown in Figure 17.30. The clock speed increase makes it difficult to secure the required time for ACK generation and data transmit procedure. I2C mode supports a function of wait-state insertion to secure this required time and a function of clock synchronization with a wait-state inserted by other devices.

The SWC bit in the UiSMR2 register is used to insert a wait-state for ACK generation (i = 0 to 2). When the SWC bit is 1 (hold the SCLi pin low after the eighth bit is received), the SCLi pin is held low on the falling edge of the eighth bit of the SCLi. When the SWC bit is 0 (no wait-state/wait-state cleared), the SCLi line is released.

When the SWC2 bit in the UiSMR2 register is 1 (hold the SCLi pin low), the SCLi pin is forced low even during transmission or reception. When the SWC2 bit is 0 (output the transmit/receive clock at the SCLi pin), the SCLi line is released to output the transmit/receive clock.

The SWC9 bit in the UiSMR4 register is used to insert a wait-state for checking received acknowledge bits. While the CKPH bit in the UiSMR3 register is 1 (clock delayed), when the SWC9 bit is set to 1 (hold the SCLi pin low after the ninth bit is received), the SCLi pin is held low on the falling edge of the ninth bit of the SCLi. When the SWC9 bit is set to 0 (no wait-state/wait-state cleared), the SCLi line is released.
Figure 17.33 Wait-state Insertion Using the SWC or SWC9 Bit (i = 0 to 2)

The CSC bit in the UiSMR2 register is used to synchronize an internally generated clock with the clock applied to the SCLi pin. For example, if a wait-state is inserted from another device, the two clocks are not synchronized. While the CSC bit is 1 (clock synchronization enabled) and the internal clock is held high, when a high at the SCLi pin changes to low, the internal clock becomes low in order to reload the value of the UiBRG register and to resume counting. While the SCLi pin is held low, when the internal clock changes from low to high, the count is stopped until the SCLi pin becomes high. That is, the UARTi transmit/receive clock is the logical AND of the internal clock and the SCLi. The synchronized period starts from one clock prior to the first synchronized clock and ends when the ninth clock is completed. The CSC bit can be set to 1 only when the CKDIR bit in the UiMR register is 0 (internal clock).

The SCLHI bit in the UiSMR4 register is used to leave the SCLi pin open when another master generates a STOP condition while the master is in transmit/receive operation. If the SCLHI bit is set to 1 (stop SCLi output), the SCLi pin is open (the pin is high-impedance) when a STOP condition is detected and the clock output is stopped.
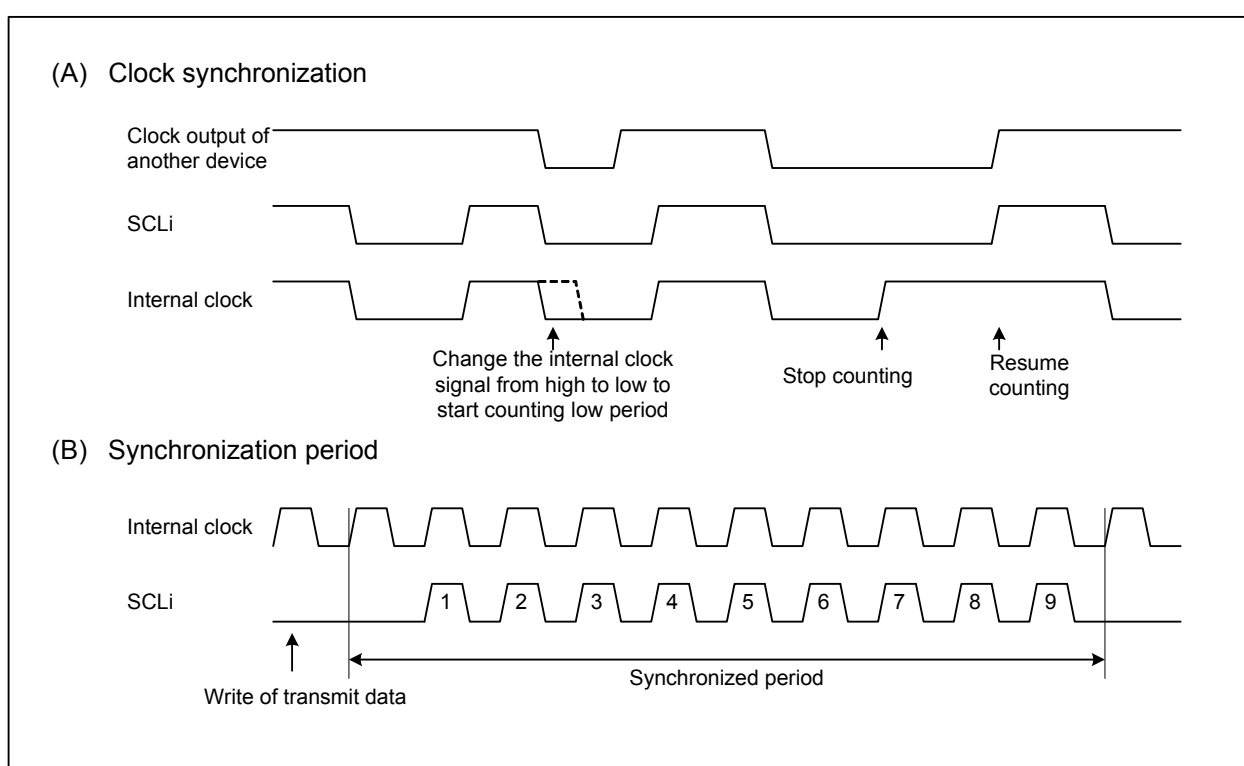

Figure 17.34 Clock Synchronization (i = 0 to 2)

17.3.5   SDA Output

Values set to bits 8 to 0 (D8 to D0) in the UiTB register are output starting from D7 to D0, and lastly D8, which is a bit for the acknowledge signal (i = 0 to 2). When transmitting, D8 should be set to 1 to free the bus. When receiving, D8 should be set to ACK or NACK.

Bits DL2 to DL0 in the UiSMR3 register set a delay time of the SDAi on the falling edge of the SCLi. Based on the UiBRG count source, the delay time can be selected from zero cycles (no delay) or two to eight cycles.

The SDAi pin can be high-impedance at any given time once the SDHI bit in the UiSMR2 register is set to 1 (stop the output). Output at the SDAi pin is low if an I/O port is selected for the SDAi and the pin is specified as the output port after selecting I2C mode. In this case, if the SDHI bit is 1, the SDAi pin becomes high-impedance.

When the SDHI bit is rewritten while the SCLi pin is held high, a START condition or STOP condition is generated. When it is rewritten immediately before the rising edge of SCLi, arbitration lost may be accidently detected. Therefore, the SDHI bit should be rewritten so the SDAi pin level changes while the SCLi pin is low.

17.3.6   SDA Input

When the IICM2 bit in the UiSMR2 register is 0 (use ACK/NACK interrupt), the first 8 bits of received data (D7 to D0) are stored into bits 7 to 0 in the UiRB register and the ninth bit (ACK/NACK) is stored into bit 8 (i = 0 to 2).

When the IICM2 bit is 1, the first 7 bits of received data (D7 to D1) are stored into bits 6 to 0 in the UiRB register and eighth bit (D0) is stored into bit 8.

If the IICM2 bit is 1 and the CKPH bit in the UiSMR3 register is 1 (clock delayed), the same data that is set when the IICM2 bit is 0 can be read. To read this data, read the UiRB register after data in the ninth bit is latched on the rising edge of the SCLi.

17.3.7   Acknowledge

When data is to be received in master mode, ACK is output after 8 bits are received by setting the UiTB register to 00FFh as dummy data. When the STPSEL bit in the UiSMR4 register is 0 (select serial I/O circuit) and the ACKC bit is 1 (ACK data output), the value of the ACKD bit is output at the SDAi pin (i = 0 to 2).

If the IICM2 bit is 0, a NACK interrupt request is generated when the SDAi pin is high on the rising edge of the ninth bit of the SCLi. An ACK interrupt request is generated when the SDAi pin is low.

When the DMA request source is "UARTi receive interrupt request or ACK interrupt request", the DMA transfer starts when an ACK is detected.

17.3.8   Transmit/Receive Operation Reset

When the CKDIR bit in the UiMR register is 1 (external clock), the STC bit in the UiSMR2 register is 1 (initialize the circuit), and a START condition is detected, the following three operations are performed (i = 0 to 2):

• The transmit register is reset and the UiTB register value is transferred to the transmit register. New data transmission starts on the falling edge of the first bit of the next SCLi as transmit clock. The transmit register value before the reset is output at the SDAi pin in the period from the falling edge of the SCLi until the first data output.

• The receive register is reset and the new data reception starts on the falling edge of the first bit of the next SCLi.

• The SWC bit in the UiSMR2 register becomes 1 (hold the SCLi pin low after the eighth bit is received).

The TI bit in the UiC1 register does not change when using this function to start the UARTi transmission/reception.

17.4   Special Mode 2

Special mode 2 enables serial communication between one or multiple masters and multiple slaves. The $\overline{\text{SSi}}$ input pin controls serial bus communication (i = 0 to 2). Table 17.14 lists specifications of special mode 2.

Table 17.14   Special Mode 2 Specifications

Item	Specification
Data format	8-bit character length
Transmit/receive clock	• The CKDIR bit in the UiMR register is set to 0 (internal clock) (i = 0 to 2): $$\frac{fx}{2(m+1)} \qquad fx = \text{f1, f8, f2n}\quad m\text{: UiBRG register setting value, 00h to FFh}$$ • The CKDIR bit is set to 1 (external clock): input to the CLKi pin
Transmit/receive control	SS function
Transmit start conditions	The conditions for starting data transmission are as follows [1]: • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register)
Receive start conditions	The conditions for starting data reception are as follows [1]: • The RE bit in the UiC1 register is 1 (reception enabled) • The TE bit in the UiC1 register is 1 (transmission enabled) • The TI bit in the UiC1 register is 0 (data held in the UiTB register)

Interrupt request generating timing	In transmit interrupt, one of the following conditions can be selected by setting the UiIRS bit in registers U0C1 to U2C1:
	• The UiIRS bit is 0 (transmit buffer is empty):
	  when data is transferred from the UiTB register to the UARTi transmit register (when the transmission has started)
	• The UiIRS bit is 1 (transmission is completed):
	  when data transmission from the UARTi transmit register is completed
	In receive interrupt,
	• When data is transferred from the UARTi receive register to the UiRB register (when the reception is completed)

Error detection	Overrun error [2] This error occurs when the seventh bit of the next data has been received before reading the UiRB register

Other functions	• CLK polarity
	  Rising or falling edge of the transmit/receive clock for transfer data input and output
	• Bit order selection
	  LSB first or MSB first
	• Continuous receive mode
	  Data reception is enabled by a read access to the UiRB register
	• Serial data logic inversion
	  This function logically inverses transmit/receive data
	• Clock phase selection
	  One of four combinations of transmit/receive clock polarity and phases
	• $\overline{\text{SSi}}$ input pin function
	  Output pin can be high-impedance when the $\overline{\text{SSi}}$ pin is high

Notes:
1.   When selecting an external clock, the following preconditions should be met:
      • The CLKi pin is held high when the CKPOL bit in the UiC0 register is 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge).
      • The CLKi pin is held low when the CKPOL bit is 1 (transmit data output on the rising edge of the transmit/ receive clock and receive data input on the falling edge).
2.   The UiRB register is undefined when an overrun error occurs. The IR bit in the SiRIC register does not change to 1 (interrupt requested).

Table 17.15 lists register settings in special mode 2.

Table 17.15   Register Settings in Special Mode 2 (i = 0 to 2)

Register	Bits	Function
UiMR	7 to 4	Set the bits to 0000b
	CKDIR	Set the bit to 0 in master mode and set it to 1 in slave mode
	SMD2 to SMD0	Set the bits to 001b
UiC0	UFORM	Select either LSB first or MSB first
	CKPOL	Clock phase can be set by the combination of bits CKPOL and CKPH in the UiSMR3 register
	NCH	Select an output mode for the TXDi pin
	CRD	Set the bit to 1
	TXEPT	Transmit register empty flag
	2	Set the bit to 0
	CLK1 and CLK0	Select a count source for the UiBRG register
UiC1	7 and 6	Set the bits to 00b
	UiRRM	Set the bit to 1 to use continuous receive mode
	UiIRS	Select a source for UARTi transmit interrupt
	RI	Receive complete flag
	RE	Set the bit to 1 to enable data reception
	TI	Transmit buffer empty flag
	TE	Set the bit to 1 to enable data transmission/reception
UiSMR	7 to 0	Set the bits to 00h
UiSMR2	7 to 0	Set the bits to 00h
UiSMR3	7 to 5	Set the bits to 000b
	ERR	Mode fault flag
	NODC	Set the bit to 0
	DINC	Set to 0 in master mode and set to 1 in slave mode
	CKPH	Clock phase can be set by the combination of bits CKPH and CKPOL in the UiC0 register
	SSE	Set the bit to 1
UiSMR4	7 to 0	Set the bits to 00h
UiBRG	7 to 0	Set the bit rate
UiTB	7 to 0	Set the data to be transmitted
UiRB	OER	Overrun error flag
	7 to 0	Received data is read

17.4.1 $\overline{SSi}$ Input Pin Function (i = 0 to 2)

Special mode 2 is selected by setting the SSE bit in the UiSMR3 register to 1 (SS function enabled). The $\overline{CTSi}/\overline{RTSi}/\overline{SSi}$ pin functions as $\overline{SSi}$ input.

The DINC bit in the UiSMR3 register determines which MCU performs as a master or slave.

When multiple MCUs perform as masters (multi-master system), the $\overline{SSi}$ pin setting determines which master MCU is active and when.

17.4.1.1 SS Function in Slave Mode

When the DINC bit is 1 (slave mode) while input at the $\overline{SSi}$ pin is high, the STXDi pin becomes high-impedance and the clock input at the CLKi pin is ignored. When input at the $\overline{SSi}$ pin is low, the clock input is valid and serial data is output from the STXDi pin to enable serial communication.

17.4.1.2 SS Function in Master Mode

When the DINC bit is 0 (master mode) while input at the $\overline{SSi}$ pin is high, which means there is the only one master MCU or no other master MCU is active, the MCU as master starts communication. The master provides the transmit/receive clock output at the CLKi pin. When input at the $\overline{SSi}$ pin is low, which means that there are more masters, pins TXDi and CLKi become high-impedance. This error is called a mode fault. It can be verified using the ERR bit in the UiSMR3 register. The ongoing data transmission/reception does not stop even if a mode fault occurs. To stop transmission/reception, bits SMD2 to SMD0 in the UiMR register should be set to 000b (serial interface disabled).
Figure 17.35 Serial Bus Communication Control with the $\overline{SSi}$ Pin

17.4.2   Clock Phase Setting

The CKPH bit in the UiSMR3 register and the CKPOL bit in the UiC0 register select one of four combinations of transmit/receive clock polarity and serial clock phase (i = 0 to 2).
The transmit/receive clock phase and polarity should be identical for the master device and the communicating slave device.

17.4.2.1   Transmit/Receive Timing in Master Mode

When the DINC bit is 0 (master mode), the CKDIR bit in the UiMR register should be set to 0 (internal clock) to generate the clock. Figure 17.36 shows transmit/receive timing of each clock phase.
Figure 17.36 Transmit/Receive Timing in Master Mode

17.4.2.2 Transmit/Receive Timing in Slave Mode

When the DINC bit is 1 (slave mode), the CKDIR bit in the UiMR register should be set to 1 (external clock).

When the CKPH bit is 0 (no clock delay) while input at the $\overline{SSi}$ pin is high, the STXDi pin becomes high-impedance. When input at the $\overline{SSi}$ pin is low, the conditions for data transmission are all met, but output is undefined. Then the data transmission/reception starts synchronizing with the clock. Figure 17.37 shows the transmit/receive timing.

When the CKPH bit is 1 (clock delayed) while input at the $\overline{SSi}$ pin is high, the STXDi pin becomes high-impedance. When input at the $\overline{SSi}$ pin is low, the first data is output. Then the data transmission starts synchronizing with the clock. Figure 17.38 shows the transmit/receive timing.
Figure 17.37 Transmit/Receive Timing in Slave Mode (CKPH = 0)
Figure 17.38 Transmit/Receive Timing in Slave Mode (CKPH = 1)

17.5   Notes on Serial Interface

17.5.1   Changing the UiBRG Register (i = 0 to 4)

- Set the UiBRG register after setting bits CLK1 and CLK0 in the UiC0 register. When these bits are changed, the UiBRG register must be set again.
- When a clock is input immediately after the UiBRG register is set to 00h, the counter may become FFh. In this case, it requires extra 256 clocks to reload 00h to the register. Once 00h is reloaded, the counter performs the operation without dividing the count source according to the setting.

17.5.2   Synchronous Serial Interface Mode

17.5.2.1   Selecting an External Clock

- If an external clock is selected, the following conditions must be met while the external clock is held high when the CKPOL bit in the UiC0 register is 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge), or while the external clock is held low when the CKPOL bit is 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge) (i = 0 to 4):
  - The TE bit in the UiC1 register is 1 (transmission enabled).
  - The RE bit in the UiC1 register is 1 (reception enabled). This bit setting is not required when only transmitting.
  - The TI bit in the UiC1 register is 0 (data held in the UiTB register).

17.5.2.2   Receive Operation

- In synchronous serial interface mode, the transmit/receive clock is controlled by the transmit control circuit. Set UARTi-associated registers for a transmit operation, even if the MCU is used only for receive operation (i = 0 to 4). Dummy data is output from the TXDi pin while receiving when the TXDi pin is set to output mode.

- When data is received continuously, an overrun error occurs when the RI bit in the UiC1 register is 1 (data held in the UiRB register) and the seventh bit of the next data is received in the UARTi receive shift register. Then, the OER bit in the UiRB register becomes 1 (overrun error occurred). In this case, the UiRB register becomes undefined. If an overrun error occurs, the IR bit in the SiRIC register does not change to 1.

17.5.3   Special Mode 1 (I²C Mode)

- To generate a START condition, STOP condition, or repeated START condition, set the STSPSEL bit in the UiSMR4 register to 0 (i = 0 to 2). Then, wait at least a half clock cycle of the transmit/receive clock to change the condition generate bits (STAREQ, RSTAREQ, or STPREQ bit) from 0 to 1.

17.5.4   Reset Procedure on Communication Error

Operations which result in communication errors such as rewriting function select registers during transmission/reception should not be performed. Follow the procedure below to reset the internal circuit once the communication error occurs in the following cases: when the operation above is performed by a receiver or transmitter or when a bit slip is caused by noise.

A. Synchronous Serial Interface Mode

(1) Set the TE bit in the UiC1 register to 0 (transmission disabled) and the RE bit to 0 (reception disabled) (i = 0 to 4).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 001b (synchronous serial interface mode).
(4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

B. UART Mode

(1) Set the TE bit in the UiC1 register to 0 (transmission disabled) and the RE bit to 0 (reception disabled).
(2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
(3) Set bits SMD2 to SMD0 in the UiMR register to 100b (UART mode, 7-bit character length), 101b (UART mode, 8-bit character length), or 110b (UART mode, 9-bit character length).
(4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

18. A/D Converter

The A/D converter consists of one 10-bit successive approximation A/D converter with a capacitive coupling amplifier.

A/D converted results are stored in the A/D registers corresponding to selected pins. Results are stored in the AD00 register only when the DMAC operating mode is enabled.

When the A/D converter is not in use, power consumption can be reduced by setting the VCUT bit in the AD0CON1 register to 0 (VREF disconnected). This bit setting enables the power supply from the VREF pin to the resistor ladder to stop.

Table 18.1 lists specifications of the A/D converter. Figure 18.1 shows a block diagram of the A/D converter. Figures 18.2 to 18.8 show registers associated with the A/D converter.

Table 18.1   A/D Converter Specifications

Item	Specification
A/D conversion method	Capacitance-based successive approximation
Analog input voltage [1]	0 V to AVCC (VCC)
Operating clock, ϕAD [2]	fAD, fAD divided by 2, fAD divided by 3, fAD divided by 4, fAD divided by 6, or fAD divided by 8
Resolution	8 bits or 10 bits
Operating modes	One-shot mode, repeat mode, single sweep mode, repeat sweet mode 0, repeat sweep mode 1, multi-port single sweep mode, multi-port repeat sweep mode 0, and self test mode
Analog input pins [3]	34 8 pins each for AN, AN0, AN2, and AN15 2 function-extended input pins (ANEX0 and ANEX1)

A/D conversion start conditions	• Software trigger
	  The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program
	• External trigger (retrigger is enabled)
	  An input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program
	• Hardware trigger (retrigger is enabled)
	  • Generation of a timer B2 interrupt request which has passed through the circuit to set an interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program
	  • Generation of a timer A0 interrupt request after the ADST bit is set to 1

Conversion rates per pin	• Without sample and hold function
	  49 ϕAD cycles at 8-bit resolution
	  59 ϕAD cycles at 10-bit resolution
	  including 2 ϕAD cycles for sampling time
	• With sample and hold function
	  28 ϕAD cycles at 8-bit resolution
	  33 ϕAD cycles at 10-bit resolution
	  including 3 ϕAD cycles for sampling time

Notes:
1. The analog input voltage is not dependent on whether the sample and hold function is enabled or disabled.
2. The ϕAD frequency should be as follows:
   • When VCC = 4.2 to 5.5 V, 16 MHz or below
   • When VCC = 3.0 to 4.2 V, 10 MHz or below
   • When not using the sample and hold function, 250 kHz or above
   • When using the sample and hold function, 1 MHz or above
3. When AVCC = VREF = VCC, A/D input voltage for pins AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1 should be VCC or lower.

ADST	A/D Conversion Start Bit	0: A/D conversion stopped 1: A/D conversion started [(7)]	RW
CKS0	Frequency Select Bit	(See Note 8)	RW

Notes:
1. When this register is rewritten during an A/D conversion, the converted result is undefined.
2. Set the analog input pins again after changing the A/D operating mode.
3. This bit setting is enabled in one-shot mode or repeat mode.
4. Select a port from AN, AN0, AN2, or AN15 by using bits APS1 and APS0 in the AD0CON2 register.
5. When the MSS bit in the AD0CON3 register is 1 (multi-port sweep mode enabled), set bits MD1 and MD0 to 10b for multi-port single sweep mode and 11b for multi-port repeat sweep mode 0.
6. Set bits MD1 and MD0 to 10b or 11b when the MSS bit in the AD0CON3 register is 1.
7. To use the external trigger or the hardware trigger, select the source of the trigger by setting bits TRG1 and TRG0 in the AD0CON2 register. Then set the ADST bit to 1 after setting the TRG bit to 1.
8. The ϕAD frequency should be as follows: 16 MHz or below when VCC = 5 V,
   10 MHz or below when VCC = 3.3 V

The ϕAD frequency is selected from the combination of bits CKS0, CKS1, and CKS2 shown as below:

CKS2 Bit in the AD0CON3 Register	CKS0 Bit in the AD0CON0 Register	CKS1 Bit in the AD0CON1 Register	ϕAD
0	0	0	fAD divided by 4
		1	fAD divided by 3
	1	0	fAD divided by 2
		1	fAD
1	0	0	fAD divided by 8
		1	fAD divided by 6

OPA0	External Op-Amp Connect Mode Bit [11, 12]	b7 b6 0 0 : No use of ANEX0 or ANEX1 pin (convert input at pins ANi_0 to ANi_7)	RW
OPA1		0 1 : Convert input at the ANEX0 pin 1 0 : Convert input at the ANEX1 pin 1 1 : External op-amp connected	RW

Notes:
1. When this register is rewritten during A/D conversion, the converted result is undefined.
2. This bit setting is enabled in single sweep mode, repeat sweep mode 0, repeat sweep mode 1, multi-port single sweep mode, or multi-port repeat sweep mode 0.
3. Select a port from AN, AN0, AN2, or AN15 by using bits APS1 and APS0 in the AD0CON2 register.
4. These pins are commonly used in A/D conversion when the MD2 bit is set to 1.
5. Set bits SCAN1 and SCAN0 to 11b in multi-port single sweep mode or multi-port repeat sweep mode 0.
6. When the MSS bit in the AD0CON3 register is 1 (multi-port sweep mode enabled), set the MD2 bit to 0.
7. Refer to the note on the CKS0 bit in the AD0CON0 register.
8. This bit controls the reference voltage to the A/D converter. It does not affect VREF performance of the D/A converter.
9. Do not set the VCUT bit to 0 during A/D conversion.
10. When the VCUT bit is switched from 0 to 1, wait at least 1 µs before starting A/D conversion.
11. Bits OPA1 and OPA0 can be set to 01b or 10b only in one-shot mode or repeat mode. Set them to 00b or 11b in other modes.
12. Set bits OPA1 and OPA0 to 00b when the MSS bit in the AD0CON3 register is 1 (multi-port sweep mode enabled).

MSS	Multi-port Sweep Mode Select Bit	0: Multi-port sweep mode disabled 1: Multi-port sweep mode enabled [3, 6]	RW
CKS2	Frequency Select Bit	(See Note 7)	RW
MSF0	Multi-port Sweep Status Flag [8]	b4 b3 0 0 : AN_0 to AN_7 0 1 : AN15_0 to AN15_7	RO
MSF1		1 0 : AN0_0 to AN0_7 1 1 : AN2_0 to AN2_7	RO
— (b7-b5)	Reserved	Set to 0. The read value is undefined	RW

Notes:
1. When this register is rewritten during A/D conversion, the converted result is undefined.
2. This register may be read incorrectly during A/D conversion. It should be read or written after the A/D converter stops operating.
3. To set the MSS bit to 1, the DUS bit should be also set to 1.
4. When the DUS bit is set to 1, all A/D converted results are stored into the AD00 register.
5. Configure DMAC when it is used to transfer converted results.
6. To set the MSS bit to 1:
   - Set the MD2 bit in the AD0CON1 register to 0 (mode other than repeat sweep mode 1).
   - Set bits APS1 and APS0 in the AD0CON2 register to 01b (AN15_0 to AN15_7).
   - Set bits OPA1 and OPA0 in the AD0CON1 register to 00b (no use of ANEX0 or ANEX1).
7. Refer to the note on the CKS0 bit in the AD0CON0 register.
8. This bit setting is enabled when the MSS bit is set to 1. The read value is undefined when the MSS bit is set to 0.

— (b5-b4)	Reserved	Should be written with 0	RW
— (b7-b6)	Reserved	If necessary, set to 0	RO

Notes:
1. When this register is rewritten during A/D conversion, the converted result is undefined.
2. An 8-bit read access to this register should be performed.
3. Appropriate evaluation for each system should be performed since A/D converted result for open-circuit detection varies with external circuits.
4. To use the self test assist or open-circuit detection assist, set the SMP bit in the AD0CON2 register to 1 (with sample and hold function).

— (b15-b10)	These bits are read as 0	RO

Notes:

1. If this register is read by a program while the DMAC is configured to transfer converted results, the value is undefined.
2. The register value written while the A/D converter stops operating is undefined.
3. Only the AD00 register is available when the DUS bit in the AD0CON3 register is 1 (DMAC operating mode enabled). Other registers are undefined.
4. When a converted result is transferred by DMAC at 10-bit mode, the DMAC should be set for a 16-bit transfer.

Figure 18.8 Registers AD00 to AD07

18.1   Mode Descriptions

18.1.1   One-shot Mode

In one-shot mode, the analog voltage applied to a selected pin is converted into a digital code only once. Table 18.2 lists specifications of one-shot mode.

Table 18.2   One-shot Mode Specifications

Item	Specification
Function	Converts the analog voltage applied to a pin into a digital code only once. The pin is selected by setting bits CH2 to CH0 in the AD0CON0 register, bits OPA1 and OPA0 in the AD0CON1 register, and bits APS1 and APS0 in the AD0CON2 register

Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger)
	    The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program.
	When the TRG bit is 1 (external trigger or hardware trigger)
	    Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source.
	 • When 00b is selected,
	    an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program.
	 • When 01b is selected,
	    generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
	 • When 10b is selected,
	    generation of a timer A0 interrupt request after the ADST bit is set to 1

Stop conditions	• A/D conversion is completed (the ADST bit is set to 0 when the software trigger is selected) • The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	When A/D conversion is completed, an interrupt request is generated
Input pin to be selected	One pin is selected from among AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1

Reading A/D converted result	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled)
	    Read the AD0j register corresponding to the selected pin (j = 0 to 7)
	When the DUS bit is 1 (DMAC operating mode enabled)
	    Configure the DMAC (refer to 12. "DMAC").
	    Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space.
	    Do not read the AD00 register by a program

18.1.2   Repeat Mode

In repeat mode, the analog voltage applied to a selected pin is repeatedly converted into a digital code. Table 18.3 lists specifications of repeat mode.

Table 18.3   Repeat Mode Specifications

Item	Specification
Function	Converts the analog voltage input to a pin into a digital code repeatedly. The pin is selected by setting bits CH2 to CH0 in the AD0CON0 register, bits OPA1 and OPA0 in the AD0CON1 register, and bits APS1 and APS0 in the AD0CON2 register
Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger) The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. When the TRG bit is 1 (external trigger or hardware trigger) Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source. • When 00b is selected, an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program. • When 01b is selected, generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program. • When 10b is selected, generation of a timer A0 interrupt request after the ADST bit is set to 1
Stop conditions	The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled), no interrupt request is generated. When the DUS bit is 1 (DMAC operating mode enabled), each time A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	One pin is selected from among AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1
Reading A/D converted result	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled) Read the AD0j register corresponding to the selected pin (j = 0 to 7) When the DUS bit is 1 (DMAC operating mode enabled) • When the converted result is transferred by DMAC Configure the DMAC (refer to 12. "DMAC"). Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space. Do not read the AD00 register by a program • When the converted result is transferred by a program Read the AD00 register after the IR bit in the AD0IC register becomes 1. Set the IR bit back to 0

18.1.3   Single Sweep Mode

In single sweep mode, the analog voltage applied to selected pins is converted one-by-one into a digital code. Table 18.4 lists specifications of single sweep mode.

Table 18.4   Single Sweep Mode Specifications

Item	Specification
Function	Converts the analog voltage input to a set of pins into a digital code one-by-one. The pins are selected by setting bits SCAN1 and SCAN0 in the AD0CON1 register and bits APS1 and APS0 in the AD0CON2 register

Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger)
	    The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program.
	When the TRG bit is 1 (external trigger or hardware trigger)
	    Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source.
	 • When 00b is selected,
	   an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program.
	 • When 01b is selected,
	   generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
	 • When 10b is selected,
	   generation of a timer A0 interrupt request after the ADST bit is set to 1

Stop conditions	• A/D conversion is completed (the ADST bit is set to 0 when the software trigger is selected) • The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled) when a sweep is completed, an interrupt request is generated. When the DUS bit is 1 (DMAC operating mode enabled), each time A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	Selected from a group of 2 pins (ANi_0 and ANi_1), 4 pins (ANi_0 to ANi_3), 6 pins (ANi_0 to ANi_5), or 8 pins (ANi_0 to ANi_7) (i = no value, 0, 2, 15)

Reading A/D converted result	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled)
	    Read the AD0j register corresponding to the selected pin (j = 0 to 7)
	When the DUS bit is 1 (DMAC operating mode enabled)
	    Configure the DMAC (refer to 12. "DMAC").
	    Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space.
	    Do not read the AD00 register by a program

18.1.4   Repeat Sweep Mode 0

In repeat sweep mode 0, the analog voltage applied to selected pins is repeatedly converted into a digital code. Table 18.5 lists specifications of repeat sweep mode 0.

Table 18.5   Repeat Sweep Mode 0 Specifications

Item	Specification
Function	Converts the analog voltage input to a set of pins into a digital code repeatedly. The pins are selected by setting bits SCAN1 and SCAN0 in the AD0CON1 register and APS1 and APS0 in the AD0CON2 register

Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger)
	    The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program.
	When the TRG bit is 1 (external trigger or hardware trigger)
	    Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source.
	 • When 00b is selected,
	   an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program.
	 • When 01b is selected,
	   generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
	 • When 10b is selected,
	   generation of a timer A0 interrupt request after the ADST bit is set to 1

Stop conditions	The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled), no interrupt request is generated. When the DUS bit is 1 (DMAC operating mode enabled), each time A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	Selected from a group of 2 pins (ANi_0 and ANi_1), 4 pins (ANi_0 to ANi_3), 6 pins (ANi_0 to ANi_5), or 8 pins (ANi_0 to ANi_7) (i = no value, 0, 2, 15)

Reading A/D converted result	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled)
	    Read the AD0j register corresponding to the selected pin (j = 0 to 7)
	When the DUS bit is 1 (DMAC operating mode enabled)
	 • When the converted result is transferred by DMAC
	   Configure the DMAC (refer to 12. "DMAC").
	   Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space.
	   Do not read the AD00 register by a program
	 • When the converted result is transferred by a program
	   Read the AD00 register after the IR bit in the AD0IC register becomes 1. Set the IR bit back to 0

18.1.5   Repeat Sweep Mode 1

In repeat sweep mode 1, the analog voltage applied to eight selected pins including one to four prioritized pins is repeatedly converted into a digital code. Table 18.6 lists specifications of repeat sweep mode 1.

Table 18.6   Repeat Sweep Mode 1 Specifications

Item	Specification
Function	The analog voltage applied to eight selected pins including one to four prioritized pins is repeatedly converted into a digital code. The prioritized pins are selected by setting bits SCAN1 and SCAN0 in the AD0CON1 register and bits APS1 and APS0 in the AD0CON2 register For example, when AN_0 is selected, the A/D conversion is performed in the following order: AN_0→AN_1→AN_0→AN_2→AN_0→AN_3•••

Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger)
	   The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program.
	When the TRG bit is 1 (external trigger or hardware trigger)
	   Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source.
	 • When 00b is selected,
	  an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program. Retrigger is invalid.
	 • When 01b is selected,
	  generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
	 • When 10b is selected,
	  generation of a timer A0 interrupt request after the ADST bit is set to 1

Stop conditions	The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled), no interrupt request is generated. When the DUS bit is 1 (DMAC operating mode enabled), each time A/D conversion is completed, an interrupt request is generated
Analog voltage input pins	8 (ANi_0 to ANi_7) (i = no value, 0, 2, 15)
Prioritized pin(s)	Selected from a group of 1 pin (ANi_0), 2 pins (ANi_0 and ANi_1), 3 pins (ANi_0 to ANi_2), or 4 pins (ANi_0 to ANi_3)

Reading A/D converted result	When the DUS bit in the AD0CON3 register is 0 (DMAC operating mode disabled)
	   Read the AD0j register corresponding to the selected pin (j = 0 to 7)
	When the DUS bit is 1 (DMAC operating mode enabled)
	 • When the converted result is transferred by DMAC
	  Configure the DMAC (refer to 12. "DMAC").
	  Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space.
	  Do not read the AD00 register by a program
	 • When the converted result is transferred by a program
	  Read the AD00 register after the IR bit in the AD0IC register becomes 1. Set the IR bit back to 0

18.1.6   Multi-port Single Sweep Mode

In multi-port single sweep mode, the analog voltage applied to 16 selected pins is converted one-by-one into a digital code. The DUS bit in the AD0CON3 register should be set to 1 (DMAC operating mode enabled). Table 18.7 lists specifications of multi-port single sweep mode.

Table 18.7   Multi-port Single Sweep Mode Specifications

Item	Specification
Function	Converts the analog voltage input to a set of 16 selected pins into a digital code one-by-one in the following order: AN_0 to AN_7→ANi_0 to ANi_7 (i = 0, 2, 15) The 16 pins are selected by setting bits MPS11 and MPS10 in the AD0CON4 register For example, when bits MPS11 and MPS10 are set to 10b (AN_0 to AN_7, AN0_0 to AN0_7), the analog voltage is converted into a digital code in the following order: AN_0→AN_1→AN_2→AN_3→AN_4→AN_5→AN_6→AN_7→AN0_0→•••→AN0_6→AN0_7
Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger) The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program. When the TRG bit is 1 (external trigger or hardware trigger) Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source. • When 00b is selected, an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program. • When 01b is selected, generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program. • When 10b is selected, generation of a timer A0 interrupt request after the ADST bit is set to 1
Stop conditions	• A/D conversion is completed (the ADST bit is set to 0 when the software trigger is selected) • The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	Every time A/D conversion is completed (set the DUS bit to 1)
Analog voltage input pins	A combination of pin group is selected from AN_0 to AN_7→AN15_0 to AN15_7, AN_0 to AN_7→AN0_0 to AN0_7, or AN_0 to AN_7→AN2_0 to AN2_7
Reading A/D converted result	Set the DUS bit to 1 and configure the DMAC (refer to 12. "DMAC"). Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space. Do not read the AD00 register by a program

18.1.7   Multi-port Repeat Sweep Mode 0

In multi-port repeat sweep mode 0, the analog voltage applied to 16 selected pins is repeatedly converted into a digital code. The DUS bit in the AD0CON3 register should be set to 1 (DMAC operating mode enabled). Table 18.8 lists specifications of multi-port repeat sweep mode 0.

Table 18.8   Multi-port Repeat Sweep Mode 0 Specifications

Item	Specification

Function	Converts the analog voltage input to a set of 16 selected pins into a digital code repeatedly in the following order: AN_0 to AN_7→ANi_0 to ANi_7 (i = 0, 2, 15) The 16 pins are selected by setting bits MPS11 and MPS10 in the AD0CON4 register
	  For example, when bits MPS11 and MPS10 are set to 10b (AN_0 to AN_7, AN0_0 to AN0_7),the analog voltage is converted into a digital code repeatedly in the following order:
	     AN_0→AN_1→AN_2→AN_3→AN_4→AN_5→AN_6→AN_7→AN0_0→•••→ AN0_6→AN0_7

Start conditions	When the TRG bit in the AD0CON0 register is 0 (software trigger)
	  The ADST bit in the AD0CON0 register is set to 1 (A/D conversion started) by a program.
	When the TRG bit is 1 (external trigger or hardware trigger)
	  Set bits TRG1 and TRG0 in the AD0CON2 register to select external trigger request source.
	• When 00b is selected,
	  an input signal at the $\overline{\text{ADTRG}}$ pin switches from high to low after the ADST bit is set to 1 by a program.
	• When 01b is selected,
	  generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers after the ADST bit is set to 1 by a program.
	• When 10b is selected,
	  generation of a timer A0 interrupt request after the ADST bit is set to 1

Stop conditions	The ADST bit is set to 0 (A/D conversion stopped) by a program
Interrupt request generation timing	Every time A/D conversion is completed (set the DUS bit to 1)
Analog voltage input pins	A combination of pin group is selected from AN_0 to AN_7→AN15_0 to AN15_7, AN_0 to AN_7→AN0_0 to AN0_7, or AN_0 to AN_7→AN2_0 to AN2_7
Reading A/D converted result	Set the DUS bit to 1 and configure the DMAC (refer to 12. "DMAC"). Then the A/D converted result is stored in the AD00 register after the conversion is completed. The DMAC transfers the converted result from the AD00 register to a given memory space. Do not read the AD00 register by a program

18.2   Functions

18.2.1   Resolution Selection

Resolution is selected by setting the BITS bit in the AD0CON1 register. When the BITS bit is set to 1 (10-bit precision), the A/D converted result is stored into bits 9 to 0 in the AD0i register (i = 0 to 7). When the BITS bit is set to 0 (8-bit precision), the result is stored into bits 7 to 0 in the AD0i register.

18.2.2   Sample and Hold Function

This function improves the conversion rate per pin to 28 ϕAD cycles at 8-bit resolution and 33 ϕAD cycles for 10-bit resolution. This function is available in all operating modes and is enabled by setting the SMP bit in the AD0CON2 register to 1 (with sample and hold function). Start A/D conversion after setting the SMP bit.

18.2.3   Trigger Selection

A trigger to start A/D conversion is specified by the combination of TRG bit in the AD0CON0 register and bits TRG1 and TRG0 in the AD0CON2 register. Table 18.9 lists the settings of the trigger selection.

Table 18.9   Trigger Selection Settings

Bit and Setting		Trigger
AD0CON0 register	AD0CON2 register	
TRG = 0	—	Software trigger The ADST bit in the AD0CON0 register is set to 1
TRG = 1 [1, 2]	TRG1 = 0, TRG0 = 0	External trigger Falling edge of a signal applied to the $\overline{\text{ADTRG}}$ pin
	TRG1 = 0, TRG0 = 1	Hardware trigger Generation of a timer B2 interrupt request which has passed through the circuit to set the interrupt generating frequency in the three-phase motor control timers
	TRG1 = 1, TRG0 = 0	Hardware trigger Generation of a timer A0 interrupt request

Notes:
1. A/D conversion starts when a trigger is generated while the ADST bit is 1 (A/D conversion started).
2. When an external trigger or a hardware trigger is generated during A/D conversion, the A/D converter aborts the operation in progress. Then, it restarts the operation.

18.2.4   DMAC Operating Mode

DMAC operating mode can be used in all operating modes. DMAC operating mode is highly recommended when the A/D converter is in multi-port single sweep mode or multi-port repeat sweep mode 0. When the DUS bit in the AD0CON3 register is set to 1 (DMAC operating mode enabled), all A/ D converted results are stored in the AD00 register. The DMAC transfers the data from the AD00 register to a given memory space every time A/D conversion is completed at a pin. 8-bit DMA transfer should be selected for 8-bit resolution. For 10-bit resolution, 16-bit DMA transfer should be selected. Refer to 12. "DMAC" for details.

18.2.5   Function-extended Analog Input Pins

In one-shot mode and repeat mode, pins ANEX0 and ANEX1 can be used as analog input pins by setting bits OPA1 and OPA0 in the AD0CON1 register (refer to Table 18.10). The A/D converted results of pins ANEX0 and ANEX1 are stored into registers AD00 and AD01, respectively. However, when the DUS bit in the AD0CON3 register is set to 1 (DMAC operating mode enabled), all results are stored into the AD00 register.

To use function-extended analog input pins, bits APS1 and APS0 in the AD0CON2 register should be set to 00b (AN0 to AN7, ANEX0, ANEX1 function as analog input ports) and the MSS bit in the AD0CON3 register to 0 (multi-port sweep mode disabled).

Table 18.10   Function-extended Analog Input Pin Settings

AD0CON1 Register		ANEX0	ANEX1
OPA1	OPA0		
0	0	Not used	Not used
0	1	Analog input	Not used
1	0	Not used	Analog input
1	1	Output to an external op-amp	Input from an external op-amp

18.2.6   External Operating Amplifier (Op-Amp) Connection Mode

In external op-amp connection mode, multiple analog inputs can be amplified by one external op-amp using function-extended analog input pins ANEX0 and ANEX1.

When bits OPA1 and OPA0 in the AD0CON1 register are 11b (external op-amp connected), the voltage applied to pins AN0 to AN7 is output from the ANEX0 pin. This output signal should be amplified by an external op-amp and applied to the ANEX1 pin.

The analog voltage applied to the ANEX1 pin is converted into a digital code. The converted result is stored in the corresponding AD0i register (i = 0 to 7). The conversion rate varies with the response of the external op-amp. Note that the ANEX0 pin should not be connected to the ANEX1 pin directly.

To use external op-amp connection mode, set bits APS1 and APS0 in the AD0CON2 register to 00b.

Figure 18.9 shows an example of an external op-amp connection.
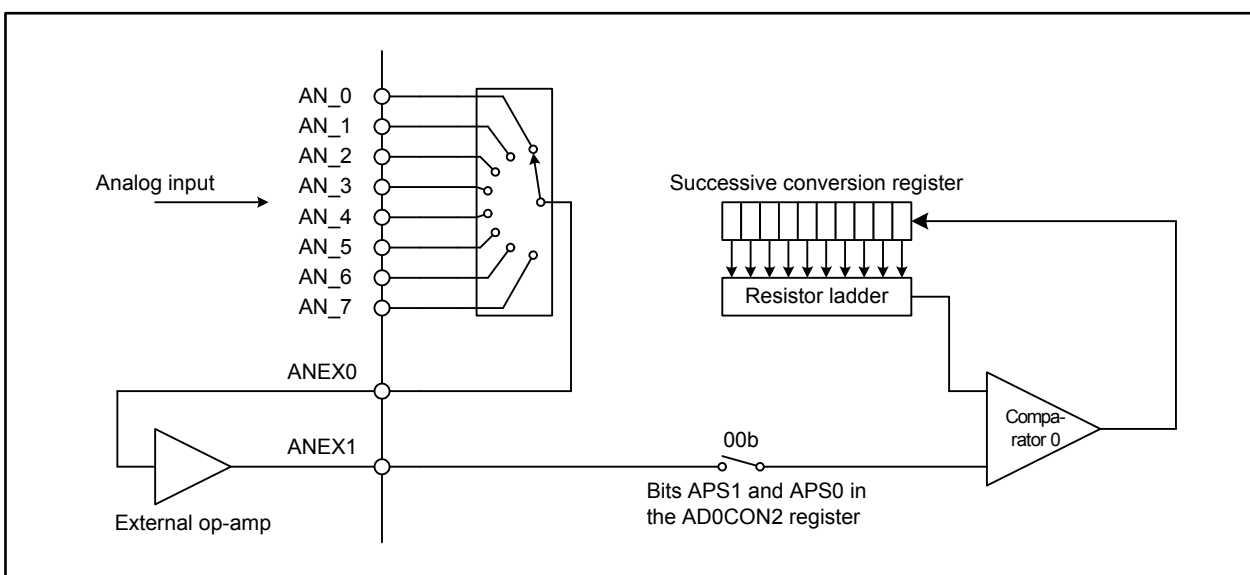

Figure 18.9   External Op-Amp Connection

18.2.7   Self Test/Open-circuit Detection Assist

This function enables the MCU to detect open-circuit in analog input pins. It also enables it to perform a self test.

Figure 18.10 shows a block diagram of open-circuit detection assist circuit.
Figure 18.10 Open-circuit Detection Assist Circuit

To detect open-circuit, the ASTSEL bit in the AD0CON5 register should be set to 0 (open-circuit detection assist). Va in Figure 18.10 above is a voltage with a value between AVCC and the A/D applied voltage in the following bit settings: the ASTEN bit is 1 (assist enabled), the ASTSEL bit is 0, and the ASTMTD bit is 0 (pull-up). If the A/D input pin is open, Va is almost equal to AVCC. When the ASTEN bit is 1, the ASTSEL bit is 0, and the ASTMTD bit is 1 (pull-down), Va is between AVSS and the A/D applied voltage. If the A/D input pin is open, Va is almost AVSS. That is, the A/D input pin is considered open if the result value of A/D conversion is almost the maximum/minimum voltage.

To enable the self test function, the ASTSEL bit in the AD0CON5 register should be set to 1 (self test assist). Va is almost equal to AVCC in the bit settings as the ASTEN bit is 1, the ASTSEL bit is 1, and the ASTMTD bit is 0. When the ASTEN bit is 1, the ASTSEL bit is 1, and the ASTMTD bit is 1, Va is almost AVSS. That is, if the result value of A/D conversion is almost the maximum/minimum voltage in each bit setting, the A/D converter is considered to be functioning normally.

18.2.8   Power Saving

When the A/D converter is not in use, power consumption can be reduced by setting the VCUT bit in the AD0CON1 to 0 (VREF disconnected). With this bit setting, the reference voltage input pin (VREF) can be disconnected from the resistor ladder, which enables the power supply from the VREF to the resistor ladder to stop.

To use the A/D converter, set the VCUT bit to 1 (VREF connected) and wait at least 1 µs before setting the ADST bit in the AD0CON0 register to 1 (A/D conversion started). Bits ADST and VCUT should not be set to 1 simultaneously. The VCUT bit should not be set to 0 during A/D conversion.

The VCUT bit does not affect VREF performance of the D/A converter (refer to Figure 18.11).
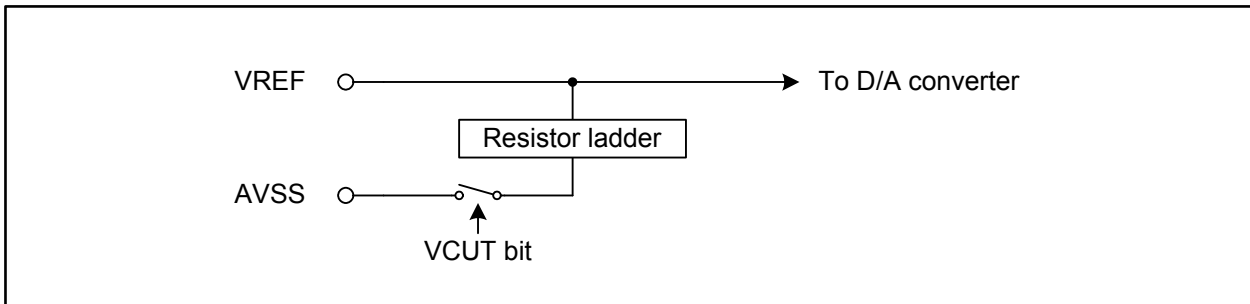

Figure 18.11 Power Supply by VCUT Bit

18.2.9   Output Impedance of Sensor Equivalent Circuit under A/D Conversion

Figure 18.12 shows an analog input pin and external sensor equivalent circuit.

To perform A/D conversion correctly, the internal capacitor (C) charging, shown in Figure 18.12, should be completed within the specified period. This period, called the sampling time, is 2 ϕAD cycles for conversion without the sample and hold function and 3 ϕAD cycles for conversion with this function.
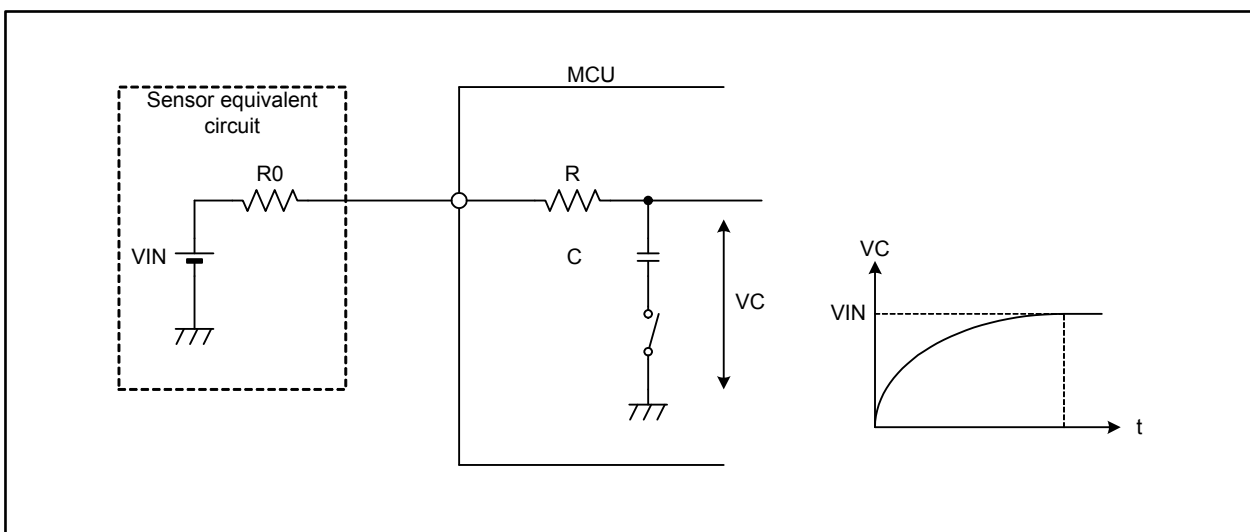

Figure 18.12 Analog Input Pin and External Sensor Equivalent Circuitry

The voltage between pins (VC) is expressed as follows:

$$VC = VIN\left\{1 - e^{-\frac{t}{C(R0+R)}}\right\}$$

When t = T and the precision (error) is x or less,

$$VC = VIN - \frac{x}{y}VIN = VIN\left(1 - \frac{x}{y}\right)$$

Thus, output impedance of the sensor equivalent circuit (R0) is determined by the following formulas:

$$e^{-\frac{T}{C(R0+R)}} = \frac{x}{y}$$

$$-\frac{T}{C(R0+R)} = \ln\frac{x}{y}$$

$$R0 = -\frac{T}{C\ln\frac{x}{y}} - R$$

where:
T[s] = Sampling time
R0[Ω] = Output impedance of the sensor equivalent circuit
VC = Potential difference between edges of capacitor C
R[Ω] = Internal resistance of the MCU
x[LSB] = Precision (error) of the A/D converter
y[step] = Resolution of the A/D converter (1024 steps at 10-bit mode, 256 steps at 8-bit mode)

When φAD = 10 MHz, the A/D conversion mode is 10-bit resolution with the sample and hold function, the output impedance (R0) with the precision (error) of 0.1 LSB or less is determined by the following formula:
Using T = 0.3 μs, R = 2.0 kΩ (reference value), C = 6.5 pF (reference value), x = 0.1, y = 1024,

$$R0 = -\frac{0.3 \times 10^{-6}}{6.5 \times 10^{-12} \times \ln\frac{0.1}{1024}} - 2.0 \times 10^3$$

$$= 2998$$

Thus, the allowable output impedance of the sensor equivalent circuit (R0), making the precision (error) of 0.1 LSB or less, should be less than 3 kΩ.
The actual error, however, is the value of absolute precision added to the 0.1 LSB mentioned above.

18.3   Notes on A/D Converter

18.3.1   Notes on Designing Boards

- Three capacitors should be placed between the AVSS pin and pins such as AVCC, VREF, and analog inputs (AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, and AN15_0 to AN15_7) to avoid erroneous operations caused by noise or latchup, and to reduce conversion errors. Figure 18.13 shows an example of pin configuration for A/D converter.

```
                                    MCU

                        AVCC

                        VREF

                                           C1 ═╪═        ═╪═ C2
        Analog input pins
                                              ═╪═ C3
                        AVSS

    Notes:
        1.  C1 ≥ 0.47 µF, C2 ≥ 0.47 µF, and C3 ≥ 100 pF (reference values)
        2.  The traces for the capacitor and the MCU should be as short and wide as physically possible.
```
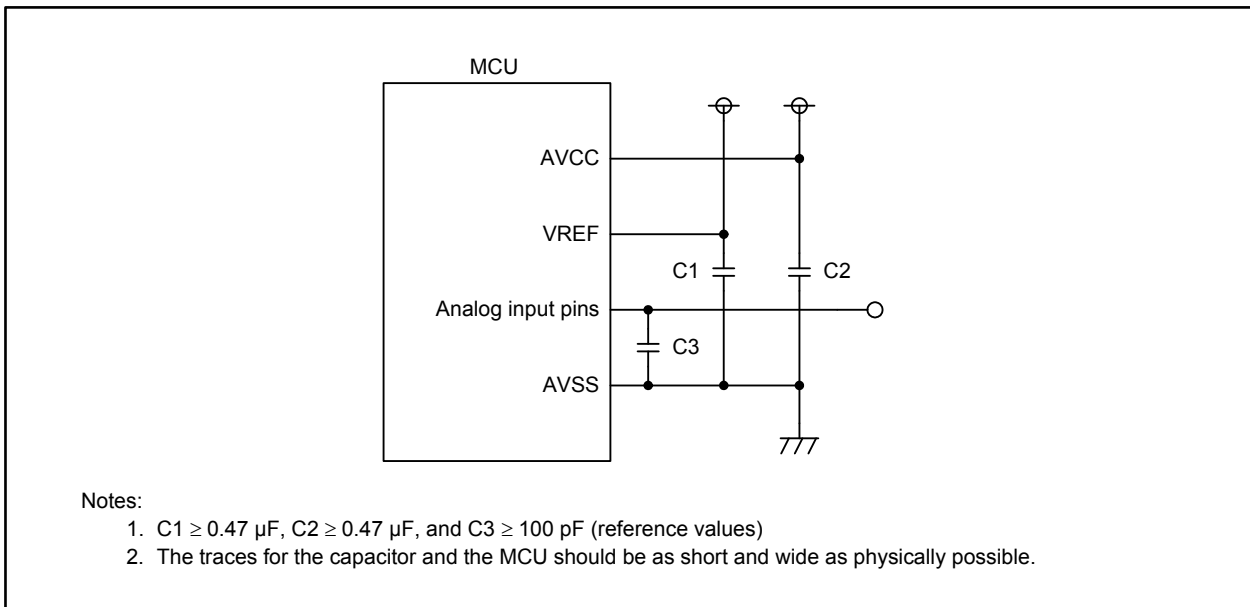

Figure 18.13 Pin Configuration for the A/D Converter

- Do not use AN_4 to AN_7 for analog input if the key input interrupt is to be used. Otherwise, a key input interrupt request occurs when the A/D input voltage becomes VIL or lower.

- When AVCC = VREF = VCC, A/D input voltage for pins AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1 should be VCC or lower.

18.3.2   Notes on Programming

- The following registers should be written while A/D conversion is stopped. That is, before a trigger occurs: AD0CON0 (except the ADST bit), AD0CON1, AD0CON2, AD0CON3, AD0CON4, and AD0CON5.

- When the VCUT bit in the AD0CON1 register is changed from 0 (VREF connected) to 1 (VREF disconnected), wait for at least 1 µs before starting A/D conversion. When not performing A/D conversion, set the VCUT bit to 0 to reduce power consumption.

- Set the port direction bit for the pin to be used as an analog input pin to 0 (input). Set the ASEL bit of the corresponding port function select register to 1 (port is used as A/D input).

- When the TRG bit in the AD0CON0 register is 1 (external trigger or hardware trigger), set the corresponding port direction bit (PD9_7 bit) for the $\overline{\text{ADTRG}}$ pin to 0 (input).

- The ϕAD frequency should be 16 MHz or lower when VCC is 4.2 to 5.5 V, and 10 MHz or lower when VCC is 3.0 to 4.2 V. It should be 1 MHz or higher when the sample and hold function is enabled. If not, it should be 250 kHz or higher.

- When A/D operating mode (bits MD1 and MD0 in the AD0CON0 register or the MD2 bit in the AD0CON1 register) has been changed, reselect analog input pins by setting bits CH2 to CH0 in the AD0CON0 register or bits SCAN1 and SCAN0 in the AD0CON1 register.

- If the AD0i register is read when the A/D converted result is stored to the register, the stored value may have an error (i = 0 to 7). Read the AD0i register after A/D conversion is completed.
  In one-shot mode or single sweep mode, read the AD0i register after the IR bit in the AD0IC register becomes 1 (interrupt requested).
  In repeat mode, repeat sweep mode 0, or repeat sweep mode 1, an interrupt request can be generated each time A/D conversion is completed when the DUS bit in the AD0CON3 register is 1 (DMAC operating mode enabled). Similar to the other modes above, read the AD00 register after the IR bit in the AD0IC register becomes 1 (interrupt requested).

- When an A/D conversion is halted by setting the ADST bit in the AD0CON0 register to 0, the converted result is undefined. In addition, the unconverted AD0i register may also become undefined. Consequently, the AD0i register should not be used just after A/D conversion is halted.

- External triggers cannot be used in DMAC operating mode. When the DMAC is configured to transfer converted results, do not read the AD00 register by a program.

- While in single sweep mode, if A/D conversion is halted by setting the ADST bit in the AD0CON0 register to 0 (A/D conversion is stopped), an interrupt request may be generated even though the sweep is not completed. To halt A/D conversion, disable interrupts before setting the ADST bit to 0.

19. D/A Converter

The MCU has two separate 8-bit R-2R resistor ladder D/A converters.

Digital code is converted to an analog voltage when a value is written to the corresponding DAi register (i = 0, 1). The DAiE bit in the DACON register determines whether the D/A conversion result is output or not. Set the DAiE bit to 1 (output enabled) to output the converted value. This bit setting disables a pull-up resistor for the corresponding port.

Analog voltage to be output (V) is calculated based on the value (n) set in the DAi register (n is a decimal number).

$$V = \frac{VREF \times n}{256} \qquad \text{(n = 0 to 255)}$$

$VREF$: reference voltage

Table 19.1 lists specifications of the D/A converter. Figure 19.1 shows a block diagram of the D/A converter. Figures 19.2 and 19.3 show registers associated with the D/A converter. Figure 19.4 shows a D/A converter equivalent circuit.

When the D/A converter is not used, set the DAi register to 00h and the DAiE bit to 0 (output disabled).

Table 19.1   D/A Converter Specifications

20. CRC Calculator

The Cyclic Redundancy Check (CRC) calculator is used for detecting errors in data blocks. A generator polynomial of CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) generates the CRC.

The CRC is a 16-bit code generated for a given set of blocks of 8-bit data. It is set in the CRCD register every time 1-byte data is written to the CRCIN register after a default value is set to the CRCD register.

Figure 20.1 shows a block diagram of the CRC calculator. Figures 20.2 and 20.3 show registers associated with the CRC. Figure 20.4 shows an example of the CRC calculation.

CRC Calculation and Setting Procedure to Generate CRC for 80C4h

● CRC Calculation for R32C

CRC: a remainder of the division as follows:

$$\frac{\text{reversed-bit-position value in the CRCIN register}}{\text{generator polynominal}}$$

Generator Polynomial: $X^{16} + X^{12} + X^5 + 1$ (1 0001 0000 0010 0001b)

● Setting Procedure

(1) Reverse the bit position of 80C4h in 1-byte units by a program

80h to 01h, C4h to 23h

(2) Set 0000h (default value in reversed bit position) in CRCD register

b15   b0
| 0000h | CRCD register
(3) Set 01h (80h in reversed bit position) in CRCIN register

b7   b0
| 01h | CRCIN register
1189h, CRC for 80h (9188h) in reversed bit position is stored into the CRCD register in the third cycle.

b15   b0
| 1189h | CRCD register
(4) Set 23h (C4h in reversed bit position) in CRCIN register

b7   b0
| 23h | CRCIN register
0A41h, CRC for 80C4h (8250h) in revered bit position is stored into the CRCD register in the third cycle.

b15   b0
| 0A41h | CRCD register
● Details of the CRC Calculation

As shown in (3) above, add 1000 0000 0000 0000 0000 0000b as 80h (1000 0000b) plus 16 digits to 0000 0000 0000 0000 0000 0000b as the default value of the CRCD register, 0000h plus eight digits to perform the modulo-2 division.

```
                                           1000 1000
1000 1000 0001 0000 1 ) 1000 0000 0000 0000 0000 0000   ←  data
                  ↑       1000 1000 0001 0000 1
        Generator Polynomial   1000 0001 0000 1000 0
                               1000 1000 0001 0000 1
                                 1001 0001 1000 1000
                                        ↑
                                       CRC
```

The modulo-2 calculation is based on the following law

0 + 0 = 0
0 + 1 = 1
1 + 0 = 1
1 + 1 = 0
-1 = 1
0001 0001 1000 1001b (1189h), the reversed-bit-position value of remainder 1001 0001 1000 1000b (9188h) can be read from the CRCD register.

When continuing on to (4) above, add 1100 0100 0000 0000 0000 0000b as C4h (1100 0100b) plus 16 digits to 1001 0001 1000 1000 0000 0000b as the remainder of (3) left in the CRCD register plus eight digits to perform the modulo-2 division.
0000 1010 0100 0001b (0A41h), the reversed-bit-position value of remainder 1000 0010 0101 0000b (8250h) can be read from the CRCD register.

21. X-Y Conversion

X-Y conversion rotates a 16 × 16-bit matrix data 90 degrees or reverses the bit position of 16-bit data.
X-Y conversion is set using the XYC register shown in Figure 21.1.
Data is written to the write-only XiR registers and converted data is read from the read-only YjR register (i = 0 to 15; j = 0 to 15). These registers are allocated to the same address. Figures 21.2 and 21.3 show registers XiR and YjR, respectively. A write/read access to registers XiR and YjR should be performed in 16-bit units from an even address. 8-bit access operation results are undefined.

Figure 21.3　Registers Y0R to Y15R

21.1　Data Conversion When Reading

Set the XYC0 bit in the XYC register to select a read mode for the YjR register. When the XYC0 bit is 0 (data rotation), bit j in the corresponding registers X0R to X15R is automatically read upon reading the YjR register (j = 0 to 15).

More concretely, upon reading bit i (i = 0 to 15) in the Y0R register, the data of bit 0 in the XiR register is read. That is, the read data of bit 0 in the Y15R register means the data of bit 15 in the X0R register and the data of bit 15 in the Y0R register is identical to that of bit 0 in the X15R register.

Figure 21.4 shows the conversion table when the XYC0 bit is 0 and Figure 21.5 shows an example of X-Y conversion.
Figure 21.4   Conversion Table (XYC0 Bit is 0)
Figure 21.5   X-Y Conversion

When the XYC0 bit is set to 1 (no data rotation), the data of each bit in the YjR register is identical to that written in the XiR register. Figure 21.6 shows the conversion table when the XYC0 bit is set to 1.
Figure 21.6   Conversion Table (XYC0 Bit is 1)

21.2   Data Conversion When Writing

Set the XYC1 bit in the XYC register to select a write mode for the XiR register.

When the XYC1 bit is set to 0 (no bit position reverse), the data is written in order. When it is set to 1 (bit position reverse), the data is written in reversed order. Figure 21.7 shows the conversion table when the XYC1 bit is set to 1.
Figure 21.7   Conversion Table (XYC1 Bit is 1)

22. Intelligent I/O

The intelligent I/O is a multifunctional I/O port for time measurement and waveform generation.
It consists of four groups each of which has one free-running 16-bit base timer and eight 16-bit registers for
time measurement or waveform generation.
Table 22.1 lists the functions and channels of the intelligent I/O.

Table 22.1   Intelligent I/O Functions and Channels

Functions		Group 0	Group 1	Group 2	Group3
Time measurement [1]	Digital filter	8 channels	8 channels	8 channels	8 channels
	Prescaler	2 channels	2 channels	2 channels	2 channels
	Gating	2 channels	2 channels	2 channels	2 channels
	Digital debounce	1 channel	1 channel	1 channel	1 channel
Waveform generation [1]	Single-phase waveform output mode	8 channels	8 channels	8 channels	8 channels
	Inverted waveform output mode	8 channels	8 channels	8 channels	8 channels
	SR waveform output mode	8 channels	8 channels	8 channels	8 channels
	Phase shift waveform output mode	8 channels	8 channels	8 channels	8 channels

Note:
   1.   The time measurement and waveform generation functions share a pin.

Each channel can be individually assigned for time measurement or waveform generation function.

Figures 22.1 to 22.4 show block diagrams of the intelligent I/O.

**Figure 22.1	Intelligent I/O Group 0 Block Diagram (j = 0 to 7)**

IT	Base Timer Interrupt Source Select Bit	0: Overflow of bit 15 or bit 9 1: Overflow of bit 14	RW

Notes:

1. Each register of the intelligent I/O is initialized after the clock with a count source selected by this register is provided. For this initializing operation, f1 should be selected as count source.
2. Do not set bits DIV4 to DIV0 to 11111b when bits BCK1 and BCK0 are set to 01b.
3. This bit setting is enabled only when bits UD1 and UD0 in the GiBCR1 register are set to 10b (two-phase pulse signal processing mode). Bits BCK1 and BCK0 should not be set to 10b in other modes.

Figure 22.6   Registers G0BCR0 to G3BCR0

Group i Base Timer Control Register 1 (i = 0 to 3)

b7	b6	b5	b4	b3	b2	b1	b0
0				0			

Symbol	Address	Reset Value
G0BCR1, G1BCR1	01A3h, 0123h	0000 0000b
G2BCR1, G3BCR1	0163h, 0263h	0000 0000b

Bit Symbol	Bit Name	Function	RW
RST0	Base Timer Reset Source Select Bit 0	0: No reset 1: The base timer is reset by synchronizing with another base timer reset [1]	RW
RST1	Base Timer Reset Source Select Bit 1	0: No reset 1: The base timer is reset by matching with the GiPO0 register [2]	RW
RST2	Base Timer Reset Source Select Bit 2	0: No reset 1: The base timer is reset by a low signal input into the $\overline{INT0}/\overline{INT1}$ pin [3]	RW
— (b3)	Reserved	Should be written with 0	RW
BTS	Base Timer Start Bit	0: Reset the base timer 1: Start counting	RW
UD0	Increment/Decrement Control Bit	b6 b5 0 0 : Increment mode 0 1 : Increment/decrement mode 1 0 : Two-phase pulse signal processing mode [4] 1 1 : Do not use this combination	RW
UD1			RW
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. The group 0 base timer is reset by synchronizing with the reset of group 1 base timer, and vice versa. The same applies to the combination of the group 2 base timer and the group 3 base timer.
2. The base timer is reset after two fBTi clock cycles when the base timer value matches the GiPO0 register setting. When the RST1 bit is 1, the value of the GiPOj register used for waveform generation should be smaller than that of the GiPO0 register (j = 1 to 7).
3. The base timer is reset by an input of low signal to the external interrupt pin selected for signals UD0Z (for groups 0 and 2) and UD1Z (for groups 1 and 3) by the IFS2 register.
4. In two-phase pulse signal processing mode, the base timer is not reset, even if the RST1 bit is 1, if the timer counter decrements after two clock cycles when the base timer value matches the GiPO0 register.

Bit Symbol	Bit Name	Function	RW
MOD0	Operating Mode Select Bit	b2 b1 b0 0 0 0 : Single-phase waveform output mode 0 0 1 : SR waveform output mode [1]	RW
MOD1		0 1 0 : Inverted waveform output mode 0 1 1 : Do not use this combination	RW
MOD2		1 0 0 : Do not use this combination 1 0 1 : Do not use this combination 1 1 0 : Do not use this combination 1 1 1 : Do not use this combination	RW
— (b3)	No register bit; should be written with 0 and read as undefined value		—
IVL	Default Output Value Select Bit [2]	0: Output low as default value 1: Output high as default value	RW
RLD	GiPOj Register Value Reload Timing Select Bit	Reload the value into the GiPOj register 0: On a write access 1: When the base timer is reset	RW
BTRE	Base Timer Reset Enable Bit [3]	Reset the base timer when 0: Bit 15 overflows 1: Bit 9 overflows [4]	RW
INV	Output Level Inversion Select Bit [5]	0: Do not invert the output level 1: Invert the output level	RW

Notes:
1. This bit setting is enabled only for even channels. In SR waveform output mode, the corresponding odd channel (the next channel after an even channel) setting is ignored. Waveforms are only output from even channels.
2. The setting value is output by a write operation to the IVL bit when the FSCj bit in the GiFS register is 0 (select the waveform generation) and the IFEj bit in the GiFE register is 1 (enable the channel j function).
3. This bit is available only in the GiPOCR0 register. Set bit 6 in registers GiPOCR1 to GiPOCR7 to 0.
4. To set the BTRE bit to 1, set bits BCK1 and BCK0 in the GiBCR0 register to 01b (timer B0 interrupt) or 11b (f1) and bits UD1 and UD0 in the GiBCR1 register to 00b (increment mode).
5. The output level inversion is the final step in the waveform generation process. When the INV bit is 1, high is output by setting the IVL bit to 0, and vice versa.

Figure 22.16 Registers G0FE to G3FE

22.1   Base Timer

The base timer is a free-running counter that counts an internally generated count source. Table 22.2 lists specifications of the base timer. Figures 22.5 to 22.16 show registers associated with the base timer. Figure 22.17 shows a block diagram of the base timer. Figures 22.18, 22.19, and 22.20 show operation examples of the base timer in increment mode, increment/decrement mode, and two-phase pulse signal processing mode, respectively.

Table 22.2   Base Timer Specifications (i = 0 to 3)

Item	Specification

Count source (fBTi)	f1 divided by 2(n+1), two-phase pulse input divided by 2(n+1)
	  n: setting value using bits DIV4 to DIV0 in the GiBCR0 register
	  n = 0 to 31; however no division when n = 31
	Timer B0 interrupt divided by 2(m+1)
	  m: setting value using bits DIV4 to DIV0 in the GiBCR0 register
	  m = 0 to 30

Count operations	• Increment • Increment/decrement • Two-phase pulse signal processing
Count start conditions	The BTS bit in the GiBCR1 register is 1 (start counting)
Count stop condition	The BTS bit in the GiBCR1 register is 0 (reset the base timer)

Reset conditions	• The base timer value matches the GiPO0 register setting
	• An input of low signal into the external interrupt pin ($\overline{INT0}$ or $\overline{INT1}$) as follows:
	  for groups 0 and 2: selected using bits IFS23 and IFS22 in the IFS2 register
	  for groups 1 and 3: selected using bits IFS27 and IFS26 in the IFS2 register
	• The overflow of bit 15 or bit 9 in the base timer

Reset value	0000h
Interrupt request	When the BTiR bit in the interrupt request register becomes 1 (interrupt requested) by the overflow of bit 9, 14, or 15 in the base timer (refer to Figure 10.16)
Read from base timer	• The GiBT register indicates a counter value while the base timer is running • The GiBT register is undefined while the base timer is being reset
Write to base timer	When a value is written while the base timer is running, the timer counter immediately starts counting from this value. No value can be written while the base timer is being reset

Other functions	• Increment/decrement mode for groups 0 and 1
	  The base timer starts counting when the BTS bit is set to 1. When the base timer reaches FFFFh, it starts decrementing. When the RST1 bit in the GiBCR1 register is 1 (the base timer is reset by matching with the GiPO0 register), the timer counter starts decrementing two counts after the base timer value matches the GiPO0 register setting. When the timer counter reaches 0000h, it starts incrementing again (refer to Figure 22.19).
	• Two-phase pulse signal processing mode for groups 0 and 1
	  Two-phase pulse signals at pins UDiA and UDiB are counted (refer to Figure 22.20).

UDiA

UDiB

The timer counter increments on all edges   The timer counter decrements on all edges
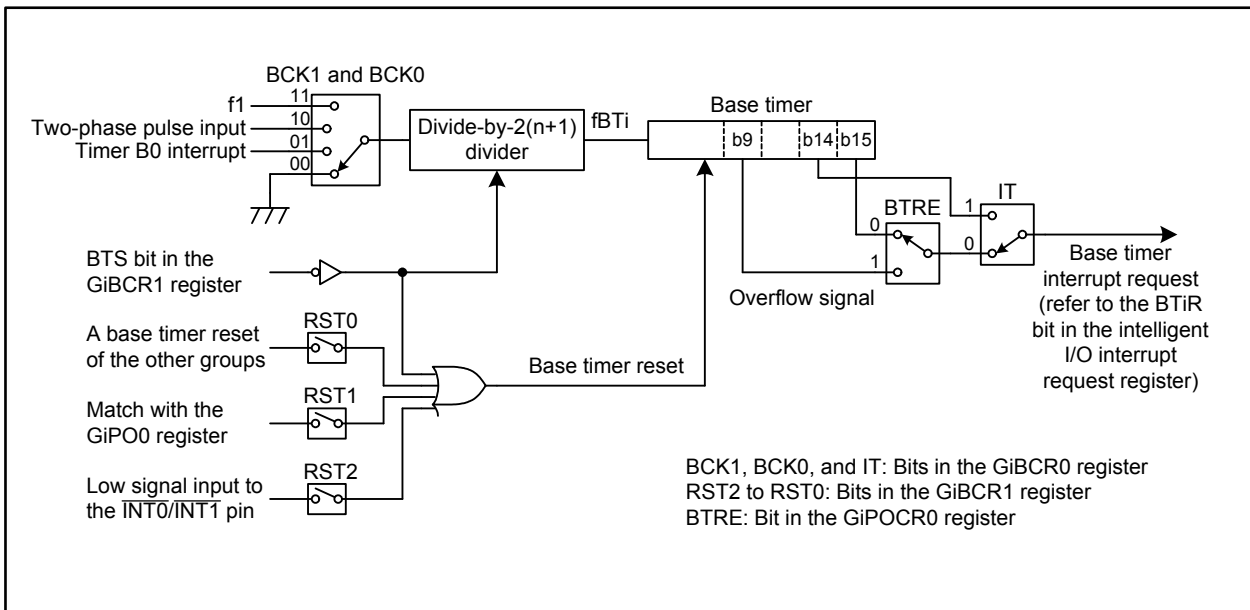

Figure 22.17 Base Timer Block Diagram (i = 0 to 3)

Table 22.3   Base Timer Associated Register Settings (Common Settings for Time Measurement, Waveform Generation, and Serial Interface) (i = 0 to 3)

Register	Bits	Function
GiBCR0	BCK1 and BCK0	Select a count source
	DIV4 to DIV0	Select a count source divide ratio
	IT	Select a base timer interrupt source
GiBCR1	RST2 to RST0	Select a timing for base timer reset
	BTS	Use this bit when each base timer individually starts counting
	UD1 and UD0	Select a count mode
GiPOCR0	BTRE	Select a source for base timer reset
GiBT	—	Read or write the base timer value

The following register settings are required to set the RST1 bit to 1 (the base timer is reset by matching with the GiPO0 register).

GiPOCR0	MOD2 to MOD0	Set to 000b (single-phase waveform output mode)
GiPO0	—	Set the reset cycle
GiFS	FSC0	Set the bit to 0 (select the waveform generation)
GiFE	IFE0	Set the bit to 1 (channel operation starts)

Bit configurations and functions vary by group.

Overflow signal of bit 15

BTiR bit in the IIOjIR register

Write 0 by a program
to set to 0

j = 7, 4, 8, or 11

This figure applies under the following conditions:
- The RST1 bit in the GiBCR1 register is 0 (the match with the GiPO0 register is not the reset source for the base timer)
- Bits UD1 and UD0 in the GiBCR1 register are 01b (increment/decrement mode)

(B) When the IT bit in the GiBCR0 register is 1
     (an interrupt request is requested by the overflow of bit 14 in the base timer)

Base timer i

Overflow signal of bit 14

BTiR bit in the IIOjIR register

j = 7, 4, 8, or 11

Write 0 by a program to set to 0

This figure applies under the following conditions:
- The RST1 bit in the GiBCR1 register is 0 (the match with the GiPO0 register is not the reset source for the base timer)
- Bits UD1 and UD0 in the GiBCR1 register are 01b (increment/decrement mode)

(C) When the RST bit in the GiBCR1 register is 1 (the base timer is reset by matching with the GiPO0 register)

Base timer i

This figure applies under the following conditions:
- The GiPO0 register value is 8000h
- Bits UD1 and UD0 in the GiBCR1 register are 01b (increment/decrement mode)

Figure 22.19 Base Timer Increment/Decrement (i = 0 to 3)

Figure 22.20 Base Timer Two-phase Pulse Signal Processing Mode (i = 0 to 3)

22.2   Time Measurement

Every time an external trigger is input, the base timer value is stored into the GiTMj register (i = 0 to 3; j = 0 to 7). Table 22.4 lists specifications of the time measurement and Table 22.5 lists its register settings. Figures 22.21 and 22.22 show operation examples of the time measurement and Figure 22.23 shows operation examples with the prescaler or gate function.

Table 22.4   Time Measurement Specifications (i = 0 to 3; j = 0 to 7)

Item	Specification
Time measurement channels	Group 0: Channels 0 to 7 Group 1: Channels 0 to 7 Group 2: Channels 0 to 7 Group 3: Channels 0 to 7
Trigger input polarity	Rising edge, falling edge, or both edges of the IIOi_j pin
Time measurement start condition	The IFEj bit in the GiFE register is 1 (enable the channel j function) while the FSCj bit in the GiFS register is 1 (select the time measurement)
Time measurement stop condition	The IFEj bit is 0 (disable the channel j function)
Time measurement timing	• Without the prescaler: every time a trigger is input • With the prescaler for channels 6 and 7: every [GiTPRk register value + 1] times a trigger is input (k = 6, 7)
Interrupt request	When the TMijR bit in the interrupt request register becomes 1 (interrupt requested) (refer to Figure 10.16)
IIOi_j input pin function	Trigger input

Other functions	• Digital filter
	  The digital filter determines a trigger input level every f1 or fBTi cycle and passes the signals holding the same level during three sequential cycles
	• Prescaler for channels 6 and 7
	  Time measurement is executed every [GiTPRk register value + 1] times a trigger is input
	• Gating for channels 6 and 7
	  This function disables any trigger input to be accepted after the time measurement by the first trigger input. However, the trigger input can be accepted again if any of following conditions are met while the GOC bit in the GiTMCRk register is 1 (the gating is cleared when the base timer matches the GiPOp register) (p = 4, 5; p = 4 when k = 6; p = 5 when k = 7):
	  • The base timer value matches the GiPOp register setting
	  • The GSC bit in the GiTMCRk register is 1

Table 22.5   Time Measurement Associated Register Settings (i = 0 to 3; j = 0 to 7; k = 6, 7)

Register	Bits	Function
GiTMCRj	CTS1 and CTS0	Select a time measurement trigger
	DF1 and DF0	Select a digital filter
	GT, GOC, GSC	Select if the gating is used
	PR	Select if the prescaler is used
GiTPRk	—	Set the prescaler value
GiFS	FSCj	Set the bit to 1 (select the time measurement)
GiFE	IFEj	Set the bit to 1 (enable the channel j function)

Bit configurations and functions vary with channels and groups.

Registers associated with the time measurement should be set after setting the base timer-associated registers.

Figure caption text within figure:

TMijR: Bits in registers IIO0IR to IIO11IR

This figure applies under the following conditions:
- Bits CTS1 and CTS0 in the GiTMCRj register are 01b (rising edge as time measurement trigger), the PR bit is 0 (prescaler disabled), and the GT bit is to 0 (gating disabled)
- Bits RST2 to RST0 in the GiBCR1 register are 000b (reset the base timer) and bits UD1 and UD0 are 00b (increment mode)

When the base timer is reset by matching with the GiPO0 register (bits RST2 to RST0 in the GiBCR1 register are 010b), the base timer becomes 0000h after it reaches the GiPO0 register setting value + 2.

Figure 22.21 Time Measurement Operation (1/2) (i = 0 to 3; j = 0 to 7)

(A) When selecting the rising edge as a time measurement trigger
(bits CTS1 and CTS0 in the GiTMCRj register are 01b)
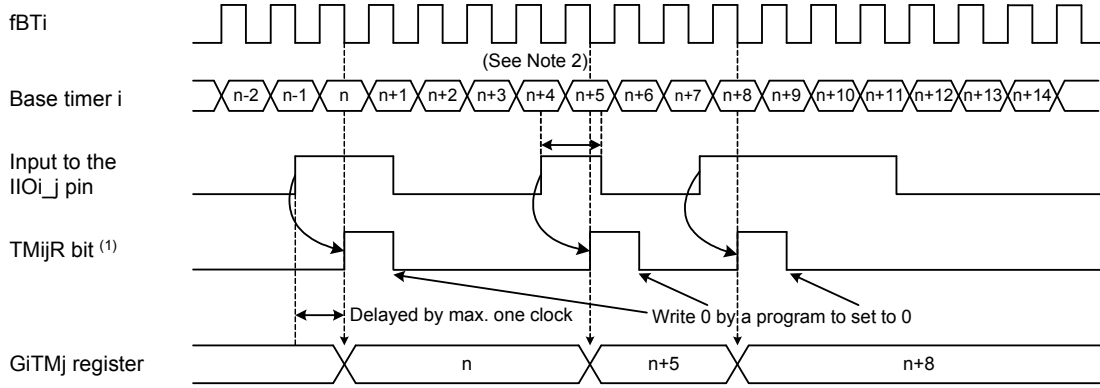

Notes:
1. Bits in registers IIO0IR to IIO11IR.
2. Input pulse applied to the IIOi_j pin requires at least 1.5 fBTi clock cycles.

(B) When selecting both edges as a time measurement trigger
(bits CTS1 and CTS0 in the GiTMCRj register are 11b)
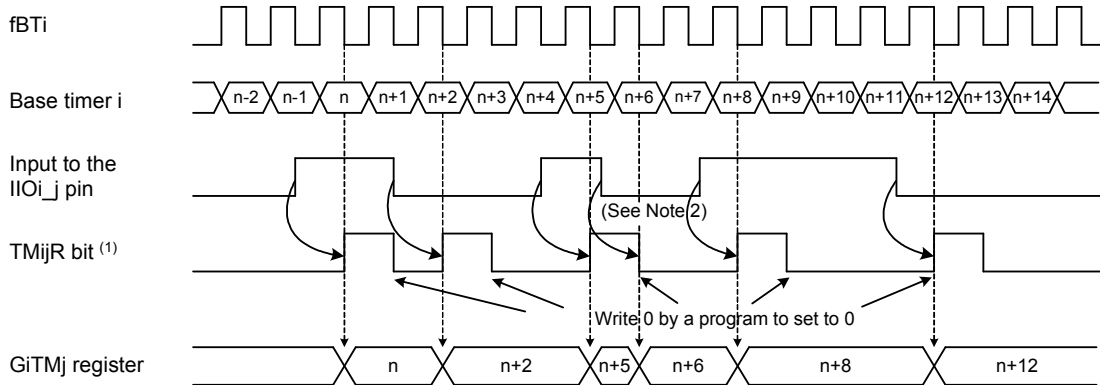

Notes:
1. Bits in registers IIO0IR to IIO11IR.
2. No interrupt occurs if the MCU receives a trigger signal when the TMijR bit is 1. However, the value of GiTMj register changes.

(C) Trigger signal when using the digital filter
(bits DF1 and DF0 in the GiTMCRj register are 10b or 11b)
Note:
1. fBTi when bits DF1 and DF0 are 10b, f1 when the bits are 11b.

Figure 22.22 Time Measurement Operation (2/2) (i = 0 to 3; j = 0 to 7)

(A) Operation with the prescaler

(the GiTPRj register is 02h and the PR bit in the GiTMCRj register is 1)
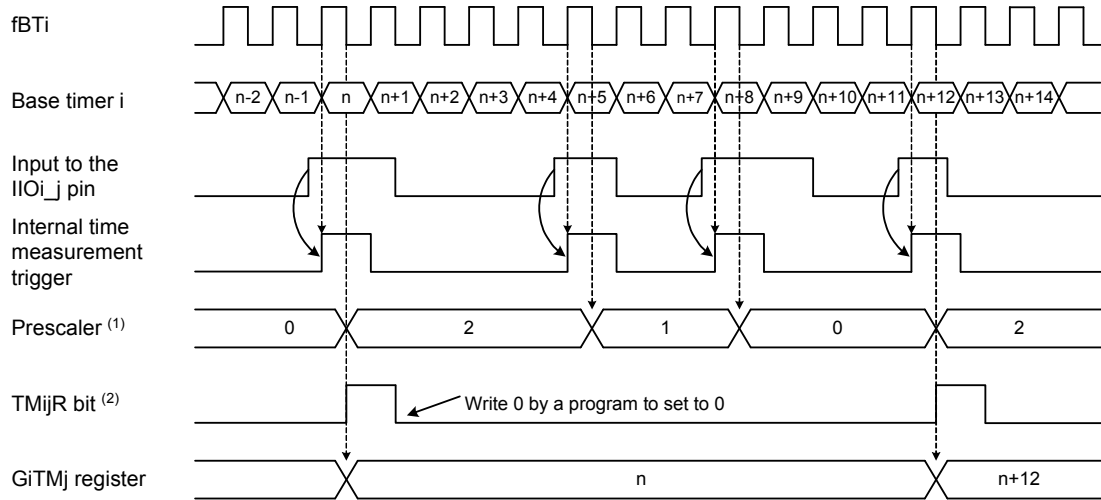

Notes:
1. This example applies to cycles following the first cycle after the PR bit in the GiTMCRj register is set to 1 (prescaler enabled).
2. Bits in registers IIO0IR to IIO11IR.

(B) Operation with the gating

(the gating is cleared by matching the base timer value with the GiPOk register setting, and bits GT and GOC in the GiTMCRj register are 1, respectively)
Note:
1. Bits in registers IIO0IR to IIO11IR.

Figure 22.23 Prescaler and Gate Operations (i = 0 to 3; j = 6, 7; k = 4, 5)

22.3   Waveform Generation

Waveforms are generated when the base timer value matches the GiPOj register setting (i = 0 to 3; j = 0 to 7).

Waveform generation has the following four modes:
- Single-phase waveform output mode
- Inverted waveform output mode
- Set/reset waveform output (SR waveform output) mode
- Phase shift waveform output mode

Table 22.6 lists registers associated with the waveform generation.

Table 22.6   Waveform Generation Associated Register Settings (i = 0 to 3; j = 0 to 7)

Register	Bits	Function
GiPOCRj	MOD2 to MOD0	Select a waveform output mode
	IVL	Select a default value
	RLD	Select a timing to reload the value into the GiPOj register
	INV	Select if output level is inverted
GiPOj	—	Set the timing to invert output waveform level
GiFS	FSCj	Set the bit to 0 (select the waveform generation)
GiFE	IFEj	Set the bit to 1 (enable the channel j function)

Bit configurations and functions vary with channels and groups.

Registers associated with the waveform generation should be set after setting the base timer-associated registers.

22.3.1   Single-phase Waveform Output Mode

The output level at the IIOi_j pin becomes high when the base timer value matches the GiPOj register (i = 0 to 3; j = 0 to 7). It switches to low when the base timer reaches 0000h. If the IVL bit in the GiPOCRj register is set to 1 (output high as default value), a high level output is provided when a waveform output starts. If the INV bit is set to 1 (invert the output level), a waveform with an inverted level is output. Refer to Figure 22.24 for details on single-phase waveform mode operation.

Table 22.7 lists specifications of single-phase waveform output mode.

Table 22.7   Single-phase Waveform Output Mode Specifications (i = 0 to 3)

Item	Specification
Output waveform [1]	• Free-running operation (when bits RST2 to RST0 in the GiBCR1 register are 000b) Cycle: $\dfrac{65536}{fBTi}$ Low level width: $\dfrac{m}{fBTi}$ High level width: $\dfrac{65536 - m}{fBTi}$ m: GiPOj register setting value (j = 0 to 7), 0000h to FFFFh • The base timer is reset by matching the base timer value with the GiPO0 register setting (when bits RST2 to RST0 are 010b) Cycle: $\dfrac{n + 2}{fBTi}$ Low level width: $\dfrac{m}{fBTi}$ High level width: $\dfrac{n + 2 - m}{fBTi}$ m: GiPOj register setting value (j = 1 to 7), 0000h to FFFFh n: GiPO0 register setting value, 0001h to FFFDh If $m \geq n + 2$, the output level is fixed to low
Waveform output start condition [2]	The IFEj bit in the GiFE register is 1 (enable the channel j function) (j = 0 to 7)
Waveform output stop condition	The IFEj bit is 0 (disable the channel j function)
Interrupt request	When the POijR bit in the intelligent I/O interrupt request register becomes 1 (interrupt requested) by matching the base timer value with the GiPOj register setting (refer to Figure 10.16)
IIOi_j output pin function	Pulse signal output

Other functions	• Default value setting
	  This function determines the starting waveform output level
	• Output level inversion
	  This function inverts the waveform output level and outputs the inverted signal from the IIOi_j pin

Notes:
1. When the INV bit in the GiPOCRj register is 1 (invert the output level), the high and low widths are inverted.
2. To use channels shared by time measurement and waveform generation, set the FSCj bit in the GiFS register to 0 (select the waveform generation).

(A) Free-running operation (bits RST2 to RST0 in the GiBCR register are 000b)

j = 0 to 7
m: GiPOj register setting value (0000h to FFFFh)
POijR: Bits in registers IIO0IR to IIO11IR

Notes:
1. Output waveform when the INV bit in the GiPOCRj register is 0 (do not invert the output level) and the IVL bit is 0 (output low as default value).
2. Output waveform when the INV bit is 0 (do not invert the output level) and the IVL bit is 1 (output high as default value).

This figure applies under the following condition:
- Bits UD1 and UD0 in the GiBCR1 register are 00b (increment mode)

(B) The base timer is reset by matching with the GiPO0 register (bits RST2 to RST0 in the GiBCR register are 010b)

j = 1 to 7
m: GiPOj register setting value (0000h to FFFFh)
n: GiPO0 register setting value (0001h to FFFDh)
POijR: Bits in registers IIO0IR to IIO11IR

This figure applies under the following conditions:
- The IVL bit in the GiPOCRj register is 0 (output low as default value) and the INV bit is 0 (do not invert the output level)
- Bits UD1 and UD0 in the GiBCR1 register are 00b (increment mode)
- m < n + 2

Figure 22.24 Single-phase Waveform Output Mode Operation (i = 0 to 3)

22.3.2   Inverted Waveform Output Mode

The output level at the IIOi_j pin is inverted every time the base timer value matches the GiPOj register setting (i = 0 to 3; j = 0 to 7).
Table 22.8 lists specifications of the inverted waveform output mode. Figure 22.25 shows an example of the inverted waveform output mode operation.

Table 22.8   Inverted Waveform Output Mode Specifications (i = 0 to 3)

Item	Specification
Output waveform	• Free-running operation (when bits RST2 to RST0 in the GiBCR1 register are 000b) Cycle: $\dfrac{65536 \times 2}{fBTi}$ High or low level width: $\dfrac{65536}{fBTi}$ m: GiPOj register setting value (j = 0 to 7), 0000h to FFFFh • The base timer is reset by matching the base timer value with the GiPO0 register setting (when bits RST2 to RST0 are 010b) Cycle: $\dfrac{2(n+2)}{fBTi}$ High or low level width: $\dfrac{n+2}{fBTi}$ n: GiPO0 register setting value, 0001h to FFFDh GiPOj register setting value (j = 1 to 7), 0000h to FFFFh If the GiPOj register setting $\geq n+2$, the output level is not inverted
Waveform output start condition [1]	The IFEj bit in the GiFE register is 1 (enable the channel j function) (j = 0 to 7)
Waveform output stop condition	The IFEj bit is 0 (disable the channel j function)
Interrupt request	When the POijR bit in the intelligent I/O interrupt request register becomes 1 (interrupt requested) by matching the base timer value with the GiPOj register setting (refer to Figure 10.16)

- m < n + 2

Figure 22.25 Inverted Waveform Output Mode Operation (i = 0 to 3)

22.3.3   Set/Reset Waveform Output Mode (SR Waveform Output Mode)

The output level at the IIOi_j pin becomes high when the base timer value matches the GiPOj register setting (i = 0 to 3; j = 0, 2, 4, 6). It becomes low when the base timer value matches the GiPOk register setting or the base timer reaches 0000h (k = j + 1). When the IVL bit in the GiPOCRj register is set to 1 (output high as default value), a high output level is provided when a waveform output starts (j = 0 to 7). When the INV bit is set to 1 (invert the output level), a waveform with inverted level is output. Refer to Figure 22.26 for details on SR waveform mode operation. Tables 22.9 and 22.10 list specifications of SR waveform output mode.

Table 22.9   SR Waveform Output Mode Specifications (i = 0 to 3) (1/2)

Item	Specification
Output waveform [1]	• Free-running operation (when bits RST2 to RST0 in the GiBCR1 register are 000b) (A) $m < n$ High level width: $\dfrac{n-m}{fBTi}$ Low level width: $\dfrac{m}{fBTi}$ (See Note 2) + $\dfrac{65536-n}{fBTi}$ (See Note 3) (B) $m \geq n$ High level width: $\dfrac{65536-m}{fBTi}$ Low level width: $\dfrac{m}{fBTi}$ m: GiPOj register setting value (j = 0, 2, 4, 6), 0000h to FFFFh n: GiPOk register setting value (k = j + 1), 0000h to FFFFh • The base timer is reset by matching with the GiPO0 register (when bits RST2 to RST0 are 010b) [4] (A) $m < n < p + 2$ High level width: $\dfrac{n+m}{fBTi}$ Low width: $\dfrac{m}{fBTi}$ (See Note 2) + $\dfrac{p+2-n}{fBTi}$ (See Note 3) (B) $m < p + 2 \leq n$ High level width: $\dfrac{p+2-m}{fBTi}$ Low level width: $\dfrac{m}{fBTi}$ (C) $m \geq p + 2$, output level is fixed to low p: GiPO0 register setting value, 0001h to FFFDh m: GiPOj register setting value (j = 2, 4, 6), 0000h to FFFFh n: GiPOk register setting value (k = j + 1), 0000h to FFFFh

Notes:
1. When the INV bit in the GiPOCRj register is 1 (invert the output level), the high and low widths are inverted.
2. Output period from a base timer reset until when the output level becomes high.
3. Output period from when the output level becomes low until the next base timer reset.
4. When the GiPO0 register resets the base timer, channel 0 and channel 1 SR waveform generation functions are not available.

- Bits UD1 and UD0 in the GiBCR1 register are 00b (increment mode)
- m < n < p + 2

Figure 22.26 SR Waveform Output Mode Operation (i = 0 to 3)

22.3.4 Phase Shift Waveform Output Mode

PWM output is phase-shifted at every channel in this mode. This mode enables functions that help to reduce switching noise and instantaneous power consumption.

The following bit settings are necessary to enable this mode; set bits MOD2 to MOD0 in the GiPOCRj register to 000b (single-phase waveform output mode), the IVL bit to 0 (output low as default value), the BTRE bit to 1 (reset the base timer when bit 9 overflows), the INV bit to 1 (invert the output level), and the IT bit in the GiBCR0 register to 0 (interrupt occurs when bit 15 or bit 9 overflows) (i = 0 to 3; j = 0 to 7).

When the phase shift waveform output mode is disabled, the output level at the IIOi_j pin becomes low if the base timer matches the GiPOj register, and becomes high when the base timer reaches 0000h (refer to (A) in Figure 22.27).

When this mode is enabled, the phase shifter controls the timing of the output level to be high. The phase shift clock to be input to the phase shifter is the count source for the base timer fBTi divided by m + 1. Every time the phase shift clock is input, each output level of the IIOi_j pin starting from the IIOi_0 sequentially becomes high (refer to (B) in Figure 22.27). The base timer overflow interrupt signal BTiR controls reloading of the divided-by-m + 1 divider and the reset of the phase shifter.

Figure 22.28 shows some more examples of output waveforms using different settings.

Note that if all channels are set to phase shift waveform output mode and the phase shift clock frequency is set to the lowest, the phase shift clock for channel 7 is not generated. Consequently, the output level at the IIOi_7 pin is held low.

When phase shift output mode is enabled, the output level of a pin cannot be fixed to low. To hold the level low, the corresponding pin should be switched to the port by the output function select register.

(A) The phase shift waveform output mode is disabled
This figure applies under the following conditions:
- The PSME bit in the GiPSCR register is 0 (phase shift waveform output mode is disabled)
- Bits MOD2 to MOD0 in the GiPOCRj register are 000b (single-phase waveform output mode), the IVL bit is 0 (output low as default value), and the INV bit is 1 (invert the output level) (j = 0 to 4)
- Bits RST2 to RST0 in the GiBCR1 register are 000b (base timer is not reset) and bits UD1 and UD0 are 00b (increment mode)

(B) The phase shift waveform output mode is enabled
This figure applies under the following conditions:
- The PSME bit in the GiPSCR register is 1 (phase shift waveform output mode is enabled) and bits PSS1 and PSS0 are 00b (pins IIOi_0 to IIOi_4 are available)
- Bits MOD2 to MOD0 in the GiPOCRj register are 000b (single-phase waveform output mode), the IVL bit is 0 (output low as default value), the BTRE bit is 1 (reset the base timer when bit 9 overflows), and the INV bit is 1 (invert the output level) (j = 0 to 4)
- The IT bit in the GiBCR0 register is 0 (interrupt occurs when bit 15 or bit 9 overflows)
- Bits RST2 to RST0 in the GiBCR1 register are 000b (base timer is not reset) and bits UD1 and UD0 are 00b (increment mode)

Figure 22.27 Phase Shift Waveform Output Mode (1/2) (i = 0 to 3)
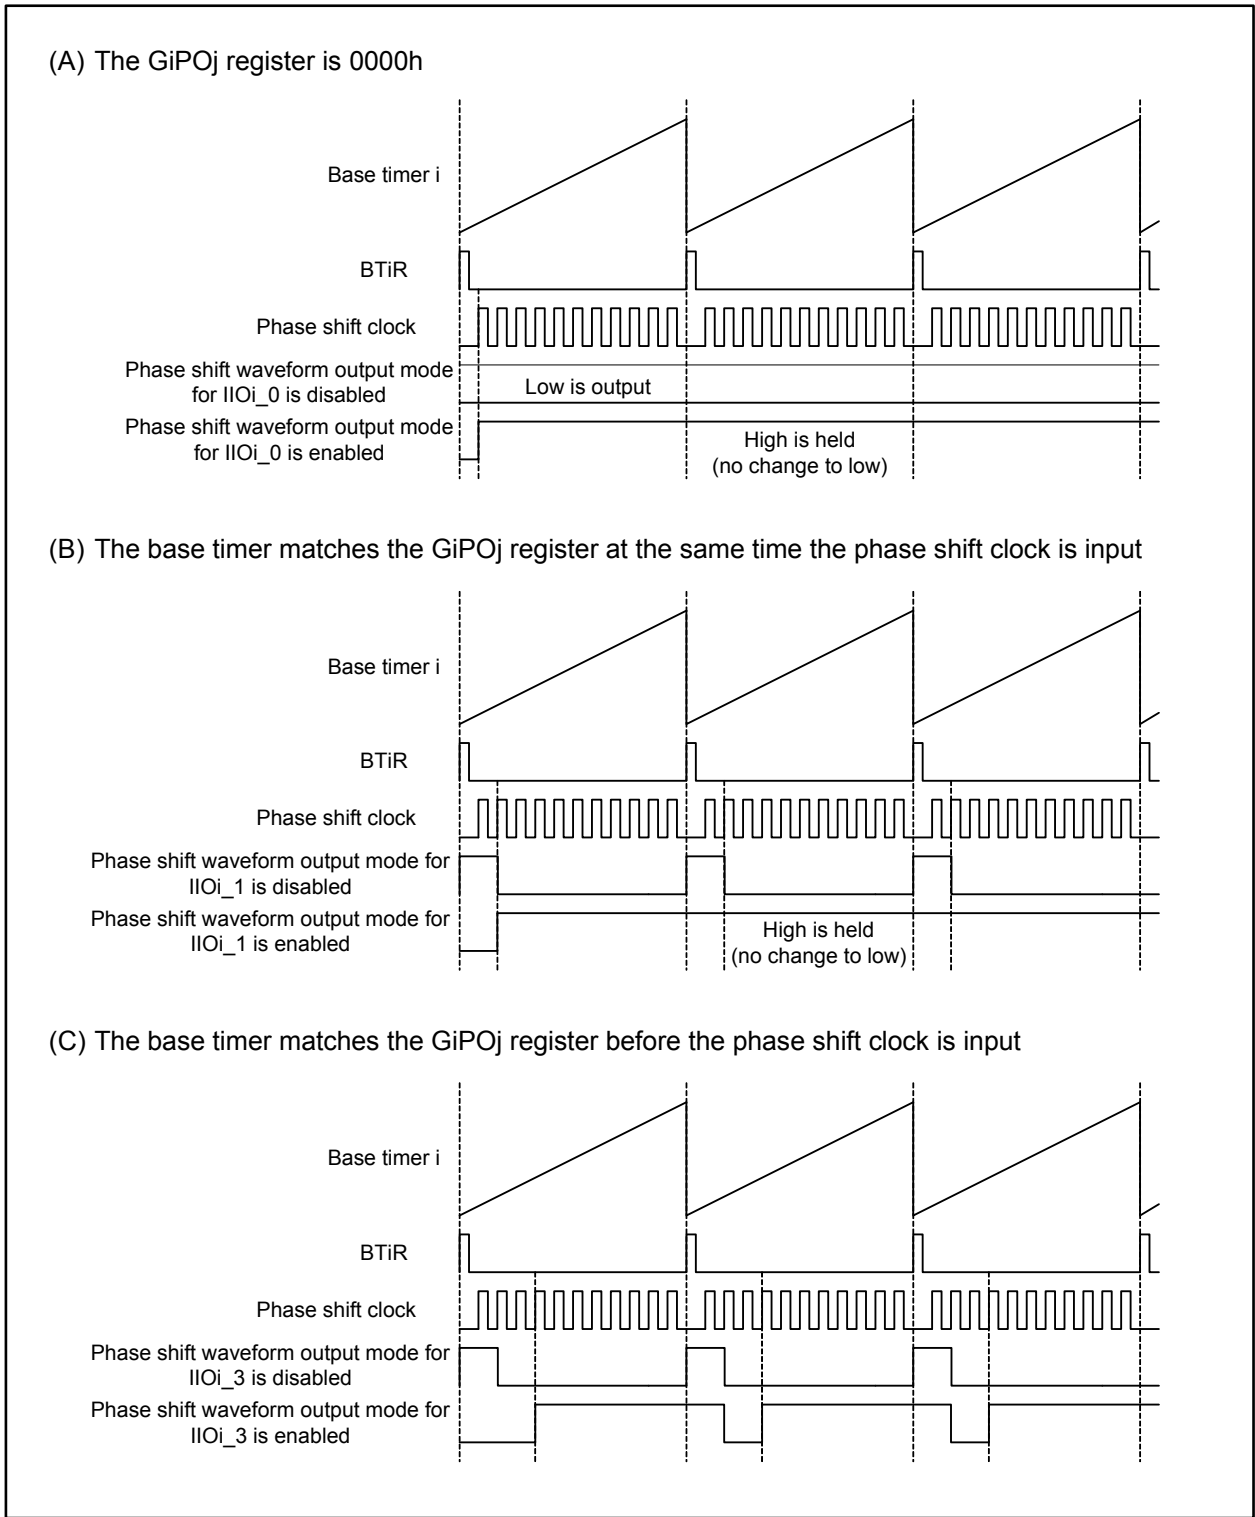

Figure 22.28 Phase Shift Waveform Output Mode (2/2) (i = 0 to 3; j = 0 to 7)

22.3.5   Digital Debounce Circuit

Pins IIO0_7 and IIO1_7 have a digital debounce function for noise reduction. This function helps to determine the signal level when the pulse becomes longer than the filter width set by a program after the signal is input on a rising or falling edge.

This function does not affect any signals that share the IIO0_7 or IIO1_7 pin.

Figure 22.29 shows the registers IC07DDR to IC37DDR.

IIOi_7 Digital Debounce Register (i = 0 to 3)

Symbol	Address	Reset Value
IC07DDR, IC17DDR	0210h, 0211h	FFh
IC27DDR, IC37DDR	0212h, 0213h	FFh

Function	Setting Range	RW
n = 00 to FEh: Only the signal whose pulse is longer than f8/ (n+1) is input to the IIOi_7 pin n = FFh: Digital debounce filtering is disabled (n = setting value)	00h to FFh	RW
Figure 22.29 Registers IC07DDR to IC37DDR

The counter for the digital debounce at the IIOi_7 pin decrements with a count source of f8 (i = 0 to 3). Every time the signal level at the pin changes, the setting value of the ICi7DDR register is reloaded to resume counting. The counted value can be read from the ICi7DDR register.

The input signal to the IIOi_7 pin is output from the digital debounce circuit on the first rising edge of f8 after the counter value becomes 00h.

A value from 00h to FEh can be set to the ICi7DDR register when using the digital debounce function. When FFh is set to this register, this function is disabled and the input signal is transmitted without being filtered.

Figure 22.30 shows an example of digital debounce filtering.

An example of digital debounce function of IIO0_7 signal (IC07DDR = 03h)

(1) The IC07DDR register is FFh after a reset. That is, the filtering is disabled, and the input signal is output without being filtered.
(2) The counter is stopped if the input and output levels are the same when setting 03h to the IC07DDR register.
(3) When detecting the input and output levels being different, the counter reloads the setting value of the IC07DDR register and starts counting.
(4) When the input and output levels become the same during counting, the counter stops. The output level does not change when the pulse width of the input signal is too short for the counter to become 00h.
(5) When detecting the input and output levels being different again, the counter reloads the setting value of the IC07DDR register and starts counting.
(6) The low signal is applied on the first rising edge of f8 after the counter reaches 00h. The output signal becomes low and the counter stops.
(7) When detecting the input and output levels being different again, the counter reloads the setting value of the IC07DDR register and starts counting.
(8) The high signal is applied on the first rising edge of f8 after the counter reaches 00h. The output signal becomes high and the counter stops.

When the IC07DDR register is set to FFh, the counter value becomes FFh after 1.5 to 2.5 cycles of f1, and the counter stops. Simultaneously, the filtering is disabled, and the input signal is output without being filtered.

Figure 22.30 Digital Debounce Filtering

23. Serial Bus Interface

The serial bus interface has three independent channels: SBI0 to SBI2.

SBIi (i = 0 to 2) has its own transmit/receive clock generator.

SBIi has the following modes:

- • Synchronous serial communication mode
- • 4-wire serial bus mode

To select a mode, set the SSUMS bit in the SSiMR2 register.

Note that each mode has its own bit names, bit symbols, and bit functions in some registers.

23.1   Synchronous Serial Communication Mode and 4-wire Serial Bus Mode

To switch between synchronous serial communication mode and 4-wire serial bus mode, set the SSUMS bit in the SSiMR2 register (i = 0 to 2).

Table 23.1 and Figure 23.1 show the specifications of synchronous serial communication mode and its block diagram, respectively. Table 23.2 and Figure 23.2 show the specifications and block diagram of 4-wire serial bus mode, respectively.

Figures 23.3 to 23.11 show the associated registers.

Table 23.1   Synchronous Serial Communication Mode Specifications (i = 0 to 2)

Item	Specification
Data format	Character length: 8 bits (fixed length)
Master/slave mode	Selectable
I/O pins	SSCKi (I/O): Clock I/O pin SSIi (input): Data input pin SSOi (output): Data output pin

Transmit/receive clocks	• When the MSS bit in the SSiCRH register is 0 (slave mode):
	   External clock (input at the SSCKi pin)
	• When the MSS bit is 1 (master mode):
	   Internal clock (output from the SSCKi pin)
	
	$\dfrac{f_{(BCLK)}}{n}$ $f_{(BCLK)}$: peripheral bus clock frequency
	         n: 4, 8, 16, 32, 64, 128, or 256

Transmit start conditions	• The TE bit in the SSiER register is 1 (transmission enabled) • The TDRE bit in the SSiSR register is 0 (unsent data left in the SSiTDR register) • The ORER bit in the SSiSR register is 0 (no overrun error) • Clock input at the SSCKi pin (applicable only when the MSS bit in the SSiCRH register is 0 (slave mode))
Receive start conditions	• The RE bit in the SSiER register is 1 (reception enabled) • The ORER bit in the SSiSR register is 0 (no overrun error) • Read operation to the SSiRDR register (applicable only when the MSS bit in the SSiCRH register is 1 (master mode)) • Clock input at the SSCKi pin (applicable only when the MSS bit in the SSiCRH register is 0 (slave mode))
Error detection	• Overrun error An overrun error occurs when the next serial data reception is completed while the RDRF bit in the SSiSR register is 1 (received data left in the SSiRDR register)
Interrupt request sources	Four interrupt request sources: transmit end, transmit data register empty, receive data register full, and overrun error [1]

Other functions	• Bit order select
	   Selectable either LSB first or MSB first
	• SSCKi clock polarity
	   Selectable either low or high for the SSCKi pin when clock is stopped
	• SSCKi clock phase
	   Combination of odd and even edges for changing and loading data

Note:
1.   Each channel has its own interrupt vector.

Figure 23.1   Block Diagram of Synchronous Serial Communication Mode (i = 0 to 2)

Table 23.2   4-wire Serial Bus Mode Specifications (i = 0 to 2)

Item	Specification
Data format	Character length: 8 to 16 bits (variable length)
Master/slave mode	Selectable
I/O pins	SSCKi (I/O): Clock I/O pin SSIi (I/O): Data I/O pin SSOi (I/O): Data I/O pin $\overline{\text{SCSi}}$ (I/O): Chip select I/O pin

Transmit/receive clocks	• When the MSS bit in the SSiCRH register is 0 (slave mode):
	   External clock (input at the SSCKi pin)
	• When the MSS bit 1 (master mode):
	   Internal clock (output from the SSCKi pin)
	
	   $\dfrac{f_{(BCLK)}}{n}$ $f_{(BCLK)}$: peripheral bus clock frequency
	   n: 4, 8, 16, 32, 64, 128, or 256

Transmit start conditions	• The TE bit in the SSiER register is 1 (transmission enabled) • The TDRE bit in the SSiSR register is 0 (unsent data left in the SSiTDR register) • The ORER bit in the SSiSR register is 0 (no overrun error) • Clock input at the SSCKi pin while the $\overline{\text{SCSi}}$ pin is low (applicable only when the MSS bit in the SSiCRH register is 0 (slave mode))
Receive start conditions	• The RE bit in the SSiER register is 1 (reception enabled) • The ORER bit in the SSiSR register is 0 (no overrun error) • Read operation to the SSiRDR register while the TE bit in the SSiER register is 0 (transmission disabled) (applicable only when the MSS bit in the SSiCRH register is 1 (master mode)) • Clock input at the SSCKi pin (applicable only when the MSS bit in the SSiCRH register is 0 (slave mode))

Error detection	• Overrun error
	  An overrun error occurs when the next serial data is received while the RDRF bit in the SSiSR register is 1 (received data left in the SSiRDR register)
	• Conflict error
	  A conflict error occurs in either of the following cases:
	      (1) An attempt to start serial communication while the $\overline{\text{SCSi}}$ pin is low (applicable when the MSS bit in the SSiCRH register is 1 (master mode))
	      (2) The $\overline{\text{SCSi}}$ pin becomes high during data transfer (applicable when the MSS bit in the SSiCRH register 0 (slave mode))

Interrupt request sources	Five interrupt request sources: transmit end, transmit data register empty, receive data register full, overrun error, and conflict error [1]

Other functions	• Bit order select
	  Selectable either LSB first or MSB first
	• SSCKi clock polarity
	  Selectable either low or high for the SSCKi pin when clock is stopped
	• SSCKi clock phase
	  Combination of odd and even edges for changing and loading data

Note:
  1.   Each channel has its own interrupt vector.

— (b1)	No register bit; should be written with 0 and read as 0		—
ORER	Overrun Error Flag [1, 3]	0: No overrun error 1: Overrun error occurred	RW
— (b4-b3)	No register bits; should be written with 0 and read as 0		—
RDRF	Receive Data Register Full Flag [1, 4]	0: No data left in the SSiRDR register 1: Received data left in the SSiRDR register	RW
TEND	Transmit End Flag [1, 5]	0: Transmission continues 1: Transmission is completed	RW
TDRE	Transmit Data Register Empty Flag [1, 6]	0: Unsent data left in the SSiTDR register 1: No data left in the SSiTDR register	RW

Notes:
1. Writing 1 to this bit has no effect. To set this bit to 0, first read the register then write 0 to the bit and write 1 to the rest of the bits.
2. This bit becomes 1 under the following conditions:
   - As an input pin, the $\overline{SCSi}$ pin is low when the SSUMS bit in the SSiMR2 register is 1 (4-wire serial bus mode), and the MSS bit in the SSiCRH register is 1 (master mode).
     or
   - As an input pin, the $\overline{SCSi}$ pin becomes high during frame transmission/reception when the SSUMS bit is 1 (4-wire serial bus mode), and the MSS bit is 0 (slave mode).
3. This flag indicates data reception ended unexpectedly because of an overrun error. This bit becomes 1 when the next serial data reception is completed while the RDRF bit is 1. Note that the data reception cannot start while this bit is 1. Data transmission cannot start either, while the MSS bit is 1 (master mode).
4. This bit becomes 0 when data is read from the SSiRDR register.
5. This bit becomes 1 when no data is left to be transmitted in the SSiTDR register before the end of the transmission of the last bit of current data. This bit becomes 0 when data is written to the SSiTDR register.
6. This bit becomes 1 when the TE bit in the SSiER register is switched from 0 (data transmission disabled) to 1 (data transmission enabled). It also becomes 1 when data is transferred from the SSiTDR register to the transmit/receive shift register. This bit becomes 0 when data is written to the SSiTDR register.

Figure 23.8   Registers SS0SR to SS2SR

SCKOS	SSCKi Pin Open Drain Output Select Bit	0: Push-pull output 1: N-channel open drain output	RW
CSS0	$\overline{SCSi}$ Pin Function Select Bit [1, 2, 3]	b5 b4 0 0 : No function as chip select 0 1 : $\overline{SCSi}$ pin as input 1 0 : $\overline{SCSi}$ pin as output 1 1 : $\overline{SCSi}$ pin as input/output [4]	RW
CSS1			RW
SCKS	SSCKi Pin Function Select Bit [2]	0: No function as I/O pin for transmit/ receive clock 1: I/O pin for transmit/receive clock	RW
BIDE	Bidirectional Mode Enable Bit [5]	0: Standard mode (two individual pins for data I/O) 1: Bidirectional mode (one common pin for data I/O)	RW

Notes:
1. Irrespective of the CSS1 and CSS0 bit setting, the $\overline{SCSi}$ pin function is not applicable when the SSUMS bit is 0.
2. Settings of the port direction register and output function select registers are prioritized over these bit settings. Set these two registers according to the function to be used.
3. To set bits CSS1 and CSS0 to 11b, first, set them to 10b, and then to 11b after the corresponding port function select register is read as 1.
4. This pin functions as output only during data transmission/reception. Otherwise, it functions as input pin.
5. When the SSUMS bit is 0, the BIDE bit setting is ignored and standard mode is always selected.

Figure 23.9   Registers SS0MR2 to SS2MR2

SSi Transmit Data Register (i = 0 to 2)

SS1TDR	044F1Fh-044F1Eh	FFFFh
SS2TDR	044F2Fh-044F2Eh	FFFFh

Function	RW
This register stores transmit data. Data should be written with the LSB in bit 0. When the character length is 9 bits or longer, write to this register in 16-bit units. When the transmit/receive shift register is detected as being empty, the transmit data stored in this register is transferred to the transmit/receive shift register to start data transmission. If the next transmit data is set to this register while the current data is being transmitted from the transmit/receive shift register, data transmission continues. When the SSUMS bit in the SSiMR2 register is 1 (4-wire serial bus mode) and the MLS bit in the SSiMR register is 1 (LSB first), the MSB-LSB reversed data is read from this register	RW

Symbol	Address	Reset Value
SS0RDR	044F07h-044F06h	FFFFh
SS1RDR	044F17h-044F16h	FFFFh
SS2RDR	044F27h-044F26h	FFFFh

Function	RW
This register stores received data. [1] When the character length is 9 bits or longer, read this register in 16-bit units. The receive data operation is completed when one frame of data received by the transmit/receive shift register is transferred to this register. The next data reception is enabled simultaneously when one sequence of the receive operation is completed. Continuous data reception is supported by this double buffer structure of the transmit/receive shift register and the SSiRDR register. The read value of bits other than that specified by bits BC3 to BC0 in the SSiMR register is undefined	RO

Note:
1. When the ORER bit in the SSiSR register becomes 1 (overrun error occurred), this register discards the current stored data, but keeps the last stored data.

Figure 23.11 Registers SS0RDR to SS2RDR

23.1.1   Transmit/Receive Clock

To use the serial bus interface in synchronous serial communication mode or 4-wire serial bus mode, set the SCKS bit in the SSiMR2 register to 1 to configure the SSCKi pin to be a transmit/receive clock pin.

(1) To use the serial bus interface in master mode
When the MSS bit in the SSiCRH register is 1 (master mode), select a transmit/receive clock from among seven internal clocks (f(BCLK) divided-by-4, -8, -16, -32, -64, -128, and -256) with bits CKS2 to CKS0.
Set the corresponding pin to SSCKi output by the output function select register and set its direction to output by the port direction register.
Since the SSCKi pin functions as clock output, the selected transmit/receive clock is output from the SSCKi pin as soon as data transmission/reception starts.

(2) To use the serial bus interface in slave mode
When the MSS bit in the SSiCRH register is 0 (slave mode), the external clock is used.
Set the corresponding pin to input by the port direction register. The SSCKi pin functions as clock input.

23.1.1.1   Transmit/Receive Clock Polarity and Phase

The relation between the transmit/receive clock polarity and phase for transmit/receive data varies with the setting combination of the SSUMS bit in the SSiMR2 register, and bits CPHS and CPOS in the SSiMR register.

Figure 23.12 shows the relation between those parameters.
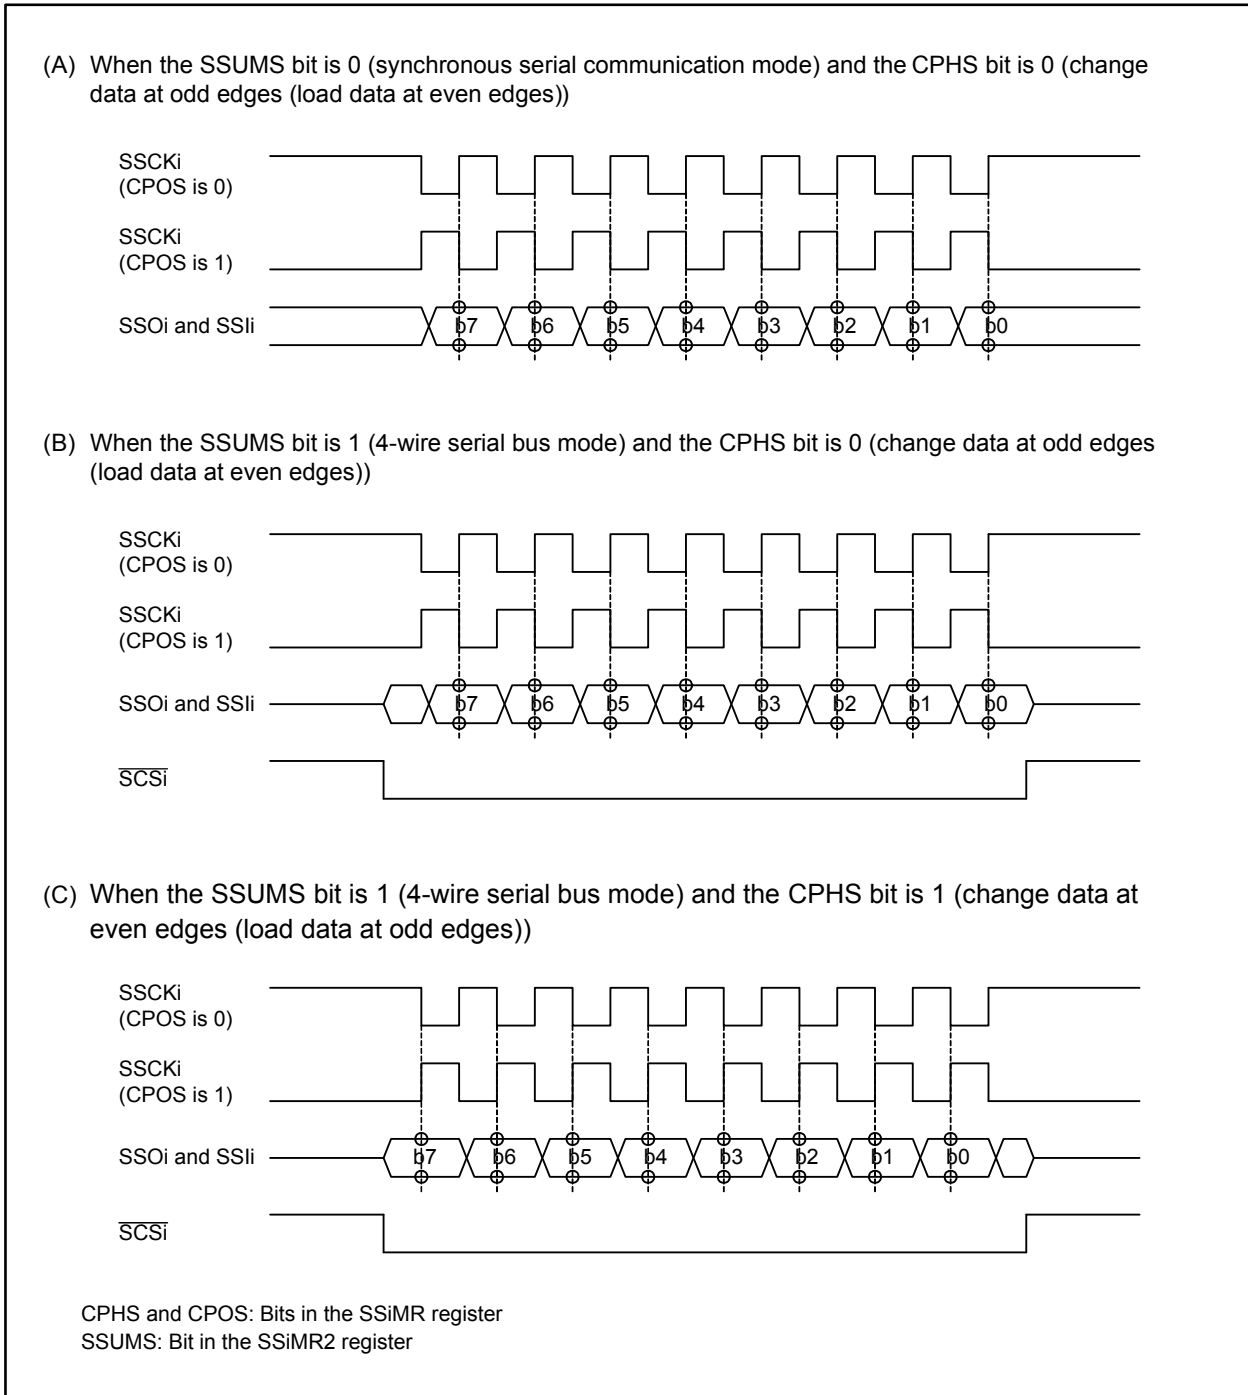

Figure 23.12 Transmit/Receive Clock Polarity and Phase of Transmit/Receive Data (i = 0 to 2)

23.1.2   Transmit/Receive Shift Register

The transmit/receive shift register transmits and receives serial data. Data transferred to the transmit/
receive shift register is shifted-out with the MSB first. Received data is shifted-in with the LSB first.
Figure 23.13 shows transmit/receive shift register operation.

23.1.2.1   Bit Order

The bit order to be transmitted/received can be selected using the MLS bit in the SSiMR register. When
the MLS bit is 1 (LSB first), transmission starts from the LSB and completes with the MSB. In a receive
operation, the first received bit is considered to be the LSB. When the MLS bit is 0 (MSB first), the bit
order transmitted is reversed and the first received bit is considered to be the MSB.

(1) Transmit operation
   When the MLS bit is 0 (MSB first), the written value is reflected in the SSiTDR register in the order
   written.
   When the MLS bit is 1 (LSB first), the written value is reflected in the SSiTDR register in the
   reversed order, that is, the reversed written value is read from the SSiTDR register.
   In both cases, however, data is transferred to the transmit/receive shift register in the transmitted
   order.

(2) Receive operation
   When the MLS bit is 0 (MSB first), the received data is transferred from the transmit/receive shift
   register to the SSiRDR register in the order received.
   When the MLS bit is 1 (LSB first), the received data is transferred from the transmit/receive shift
   register to the SSiRDR register in the reversed order.

23.1.2.2   Variable-Length Data Transmission/Reception

When the data length is less than 16 bits, the shift-in/shift-out position is changed to adjust the bit
position.
This function enables transmit/receive data with the LSB in bit 0.
Figure 23.13 Transmit/Receive Shift Register Operation

23.1.3   Data I/O Pin and SSi Shift Register

The connection pattern of the data I/O pins and the transmit/receive shift register varies with the setting combination of the MSS bit in the SSiCRH register, and bits SSUMS and BIDE in the SSiMR2 register. Figure 23.14 shows the relation between those parameters.

Figure 23.14 Data I/O Pins and Transmit/Receive Shift Register (i = 0 to 2)

23.1.4   Interrupt Requests

In synchronous serial communication mode and 4-wire serial bus mode, there are five interrupt request sources: transmit data register empty, transmit end, receive data register full, overrun error, and conflict error. Since all of these interrupt request sources are assigned to an interrupt vector table, they should be identified by flags in the interrupt handler.

Table 23.3 lists the serial bus interface interrupt request sources.

Table 23.3   Interrupt Request Sources in Synchronous Serial Communication Mode and 4-wire Serial Bus Mode

Interrupt Request Source	Generating Condition for Interrupt Requests [1, 2]
Transmit data register empty (TXI)	TIE = 1 and TDRE = 1
Transmit end (TEI)	TEIE = 1 and TEND = 1
Receive data register full (RXI)	RIE = 1 and RDRF = 1
Overrun error (OEI)	RIE = 1 and ORER = 1
Conflict error (CEI)	CEIE = 1 and CE = 1

Notes:
1. CEIE, RIE, TEIE, and TIE: Bits in the SSiER register
2. CE, ORER, RDRF, TEND, and TDRE: Bits in the SSiSR register

When one or more conditions to generate an interrupt request listed in Table 23.3 are met, a serial bus interface interrupt request is generated. The corresponding interrupt sources should be set to 0 in the interrupt handler.

However, bits TDRE (transmit data register empty) and TEND (transmit end) automatically become 0 when the next transmit data is written to the SSiTDR register. The RDRF bit (receive data register full) automatically becomes 0 when the SSiRDR register is read.

Note that if no data is being transmitted, the TDRE bit, which became 0 as mentioned above, is set back to 1 (no data left in the SSiTDR register) since the written data is immediately transferred to the transmit/receive shift register. And, if the TDRE bit is set to 0 (unsent data left in SSiTDR register) by a program, it may cause the transmission of an additional data frame.

23.1.5 Communication Modes and Pin Functions

In synchronous serial communication mode and 4-wire serial bus mode, the function of I/O pins varies with the setting combinations of the MSS bit in the SSiCRH register, and bits RE and TE in the SSiER register. The SSCKi pin is used for output in master mode, and input in slave mode. The port direction register and the port function select register need to be configured according to the direction of pins SSIi, SSOi, and SSCKi.

Table 23.4 shows the relation between communication modes and I/O pins.

Table 23.4 Communication Modes and I/O Pins (i = 0 to 2)

Communication Mode	Bit Setting					Pin State		
	SSUMS	BIDE	MSS	TE	RE	SSIi	SSOi	SSCKi
Synchronous serial communication mode	0	Disabled	0 (slave)	0	1	Input	− (1)	Input
				1	0	− (1)	Output	
				1	1	Input	Output	
			1 (master)	0	1	Input	− (1)	Output
				1	0	− (1)	Output	
				1	1	Input	Output	
4-wire serial bus mode (in standard mode)	1	0	0 (slave)	0	1	− (1)	Input	Input
				1	0	Output	− (1)	
				1	1	Output	Input	
			1 (master)	0	1	Input	− (1)	Output
				1	0	− (1)	Output	
				1	1	Input	Output	
4-wire bus communication mode (in bidirectional mode) (2)	1	1	0 (slave)	0	1	− (1)	Input	Input
				1	0	− (1)	Output	
			1 (master)	0	1	− (1)	Input	Output
				1	0	− (1)	Output	

Notes:
1. This pin can be used as a programmable I/O port.
2. In 4-wire bus communication mode (in bidirectional mode), do not use the following combination: TE bit is 1 and RE bit is 1.

  SSUMS and BIDE: Bits in the SSiMR2 register
  MSS: Bit in the SSiCRH register
  TE and RE: Bits in the SSiER register

23.1.6 Synchronous Serial Communication Mode

23.1.6.1 Initialization of Synchronous Communication Mode

Figure 23.15 shows the initialization procedure of synchronous serial communication mode. Set the TE bit in the SSiER register to 0 (transmission disabled) and the RE bit in the SSiER register to 0 (reception disabled) before the data transmit/receive operation.

To change the communication mode or the communication data format, set bits TE and RE to 0 in advance. Note that flags RDRF and ORER and the SSiRDR register are unaffected even if the RE bit is set to 0.

Start

Register	Operation
SSiER register	Set RE bit to 0 Set TE bit to 0
SSiMR2 register	Set SSUMS bit to 0
SSiMR register	Set CPHS bit to 0 Set CPOS bit Set MLS bit
SSiCRH register	Set MSS bit

SSiCRH register	Set bits CKS2 to CKS0 Set RSSTP bit

SSiSR register ORER bit is 1? — No

Yes

| SSiSR register | Set ORER bit to 0 |
| SSiER register | Set RE bit to 1
(in receive operation) or
TE bit to 1
(in transmit operation),
Set TEIE bit
Set bits RIE and TIE |

End

Figure 23.15 Initialization Procedure in Synchronous Communication Mode (i = 0 to 2)

23.1.6.2 Data Transmission

Figure 23.16 shows an example of the transmit operation in synchronous serial communication mode. During data transmission, the serial bus interface operates as described below.

When operating in master mode, an internally generated clock as a transmit/receive clock is output from the SSCKi pin. When operating in slave mode, the transmit/receive clock is a clock input from the SSCKi pin. In both cases, transmit data is output synchronized with the transmit/receive clock.

After setting the TE bit in the SSiER register to 1 (transmission enabled), if transmit data is written to the SSiTDR register, the TDRE bit in the SSiSR register automatically becomes 0 (unsent data left in the SSiTDR register), and data in the SSiTDR register is transferred to the transmit/receive shift register. Then the TDRE bit becomes 1 (no data left in the SSiTDR register) and data transmission starts. And, if the TIE bit in the SSiER register is 1 (transmit data register empty interrupt enabled), a transmit data empty interrupt request (TXI) is generated.

When the TDRE bit is 0, after transmitting one frame of data, the data is transferred from the SSiTDR register to the transmit/receive shift register to start the next data transmission. When the TDRE bit is 1, after transmitting the eighth bit of data, the TEND bit in the SSiSR register becomes 1 (transmission is completed). And, if the TEIE bit in the SSiER register is 1 (transmit end interrupt enabled), a transmit end interrupt request (TEI) is generated.

After data transmission is completed, the SSCKi pin is fixed to the level specified by the CPOS bit in the SSiMR register.

Note that data cannot be transmitted while the ORER bit in the SSiSR register is 1 (overrun error occurred). Set the ORER bit to 0 before data transmission.

Figure 23.17 shows an example of data transmission procedure in synchronous serial communication mode.

Transmit operation example in synchronous serial communication mode

Note:
1. This figure applies under the following conditions:
   - The MSS bit in the SSiCRH register is 1 (master mode).
   - The CPHS bit in the SSiMR register is 0 (change data at odd edges (load data at even edges)).
   - The CPOS bit in the SSiMR register is 0 (high when clock is stopped).
   - The MLS bit in the SSiMR register is 1 (LSB first).
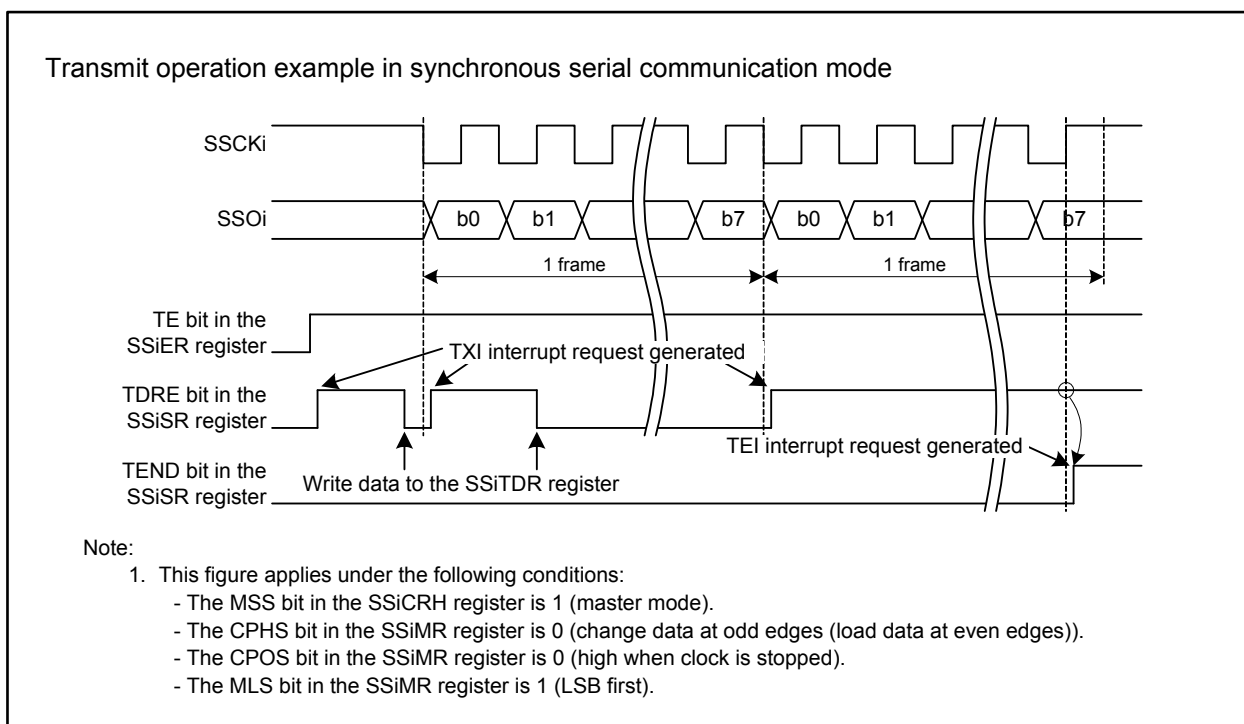

Figure 23.16 Transmit Operation Example in Synchronous Serial Communication Mode (i = 0 to 2)
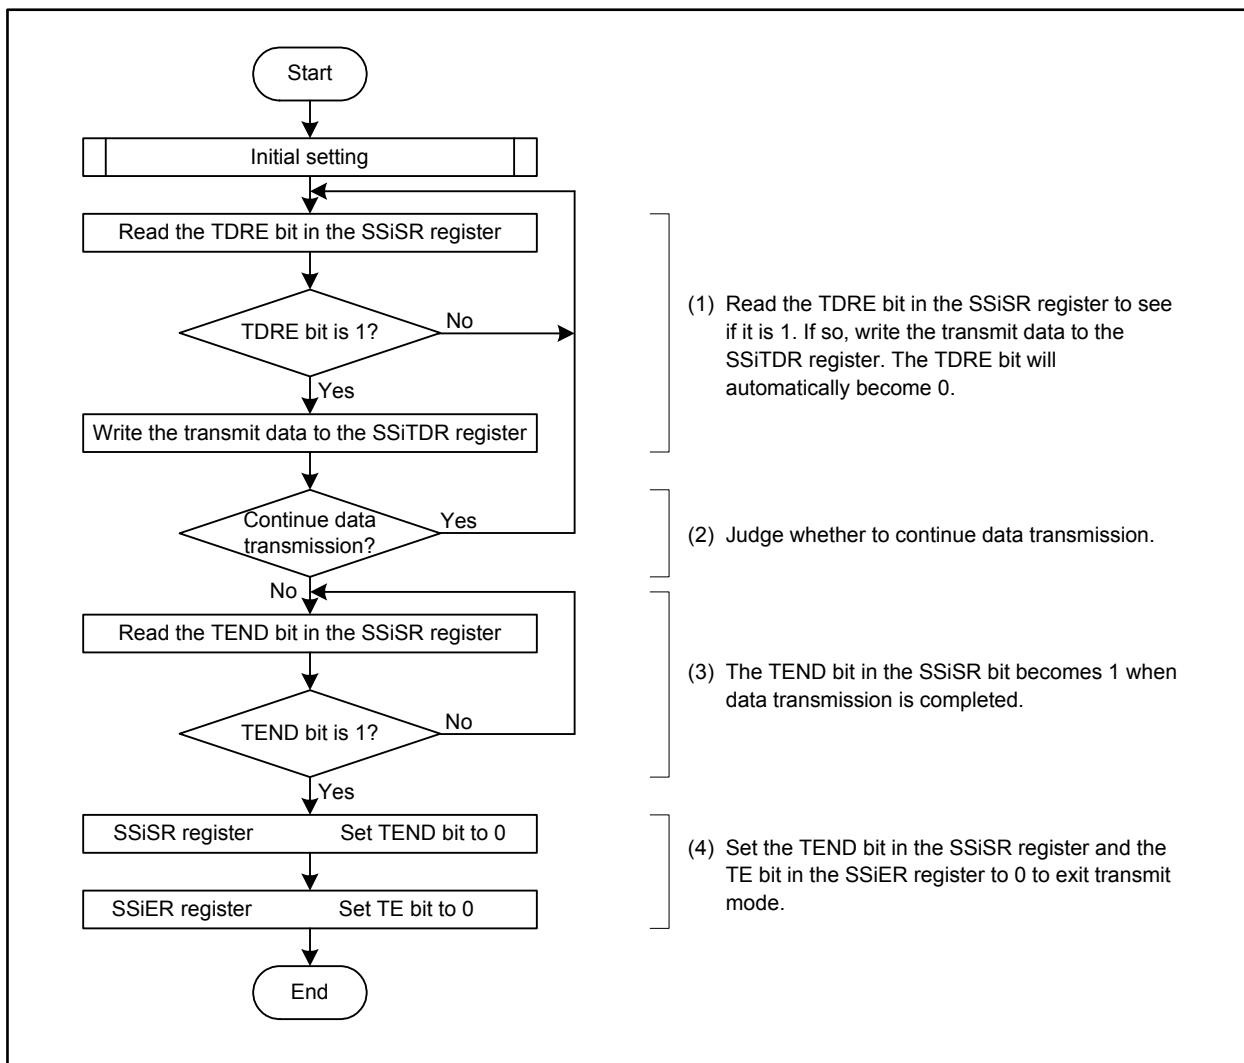

Figure 23.17 Data Transmission Example in Synchronous Serial Communication Mode (i = 0 to 2)

23.1.6.3   Data Reception

Figure 23.18 shows an example of the receive operation in synchronous serial communication mode. During data reception, the serial bus interface operates as described below.

When operating in master mode, an internally generated clock as transmit/receive clock is output from the SSCKi pin. When operating in slave mode, the transmit/receive clock is a clock input from the SSCKi pin. In both cases, receive data is input synchronized with the transmit/receive clock.

In master mode, a dummy read of the SSiRDR register evokes the receive clock output to start data reception.

When the eighth bit of data is received, the RDRF bit in the SSiSR register becomes 1 (received data left in the SSiRDR register) and the received data is stored into the SSiRDR register. And, if the RIE bit in the SSiER register is 1 (receive data register full interrupt/overrun error interrupt enabled), a receive data register full interrupt request (RXI) is generated. When the SSiRDR register is read, the RDRF bit automatically becomes 0 (no data left in the SSiRDR register).

To end the receive data operation in master mode, set the RSSTP bit in the SSiCRH register to 1 (receive operation ended after receiving the current frame) before reading the data of the second to last frame from the SSiRDR register. Then the transmit/receive clock stops when the last frame reception is completed. When the clock stops, set the RE bit in the SSiER register to 0 (reception disabled) and the RSSTP bit to 0 (receive operation continued after receiving the current frame) and read the data of the last frame. Note that if the SSiRDR register is read while the RE bit is 1, then the receive clock is output again.

If the eighth bit of the data is received when the RDRF bit is 1, the ORER bit in the SSiSR register becomes 1 (overrun error occurred), and the receive operation stops. Note that data cannot be received while the ORER bit is 1. Set the ORER bit to 0 before resuming data reception.

Figure 23.19 shows an example of the data reception procedure in master mode of synchronous communication mode.

Receive operation example in synchronous serial communication mode

Note:
   1. This figure applies under the following conditions:
       - The MSS bit in the SSiCRH register is 1 (master mode).
       - The CPHS bit in the SSiMR register is 0 (change data at odd edges (load data at even edged)).
       - The CPOS bit in the SSiMR register is 0 (high when clock is stopped).
       - The MLS bit in the SSiMR register is 1 (LSB first).
Figure 23.18 Receive Operation Example in Master Mode of Synchronous Serial Communication Mode (i = 0 to 2)

Figure 23.19 Data Reception Example in Master Mode of Synchronous Serial Communication Mode (i = 0 to 2)

23.1.6.4   Data Transmission/Reception

Data transmission/reception is a combined operation of data transmission and data reception mentioned in sections 23.1.6.2 and 23.1.6.3.

Data transmission/reception starts when data is written to the SSiTDR register, and ends when the eighth bit of data is transmitted while the TDRE bit is 1 (no data left in the SSiTDR register). The data transmit/receive operation stops when the ORER bit becomes 1 (overrun error occurred) due to an error.

To switch modes from transmit mode (TE bit is 1 and RE bit is 0) or receive mode (TE bit is 0 and RE bit is 1) to transmit/receive mode (TE bit is 1 and RE bit is 1), set bits TE and RE to 0. Then, check that the TEND bit is 0 (transmission continued), the RDRF bit is 0 (no data left in the SSiRDR register), the ORER bit is 0 (no overrun error), and subsequently set bits TE and RE to 1 at the same time.

Figure 23.20 shows an example of data transmission/reception procedure in synchronous serial communication mode.
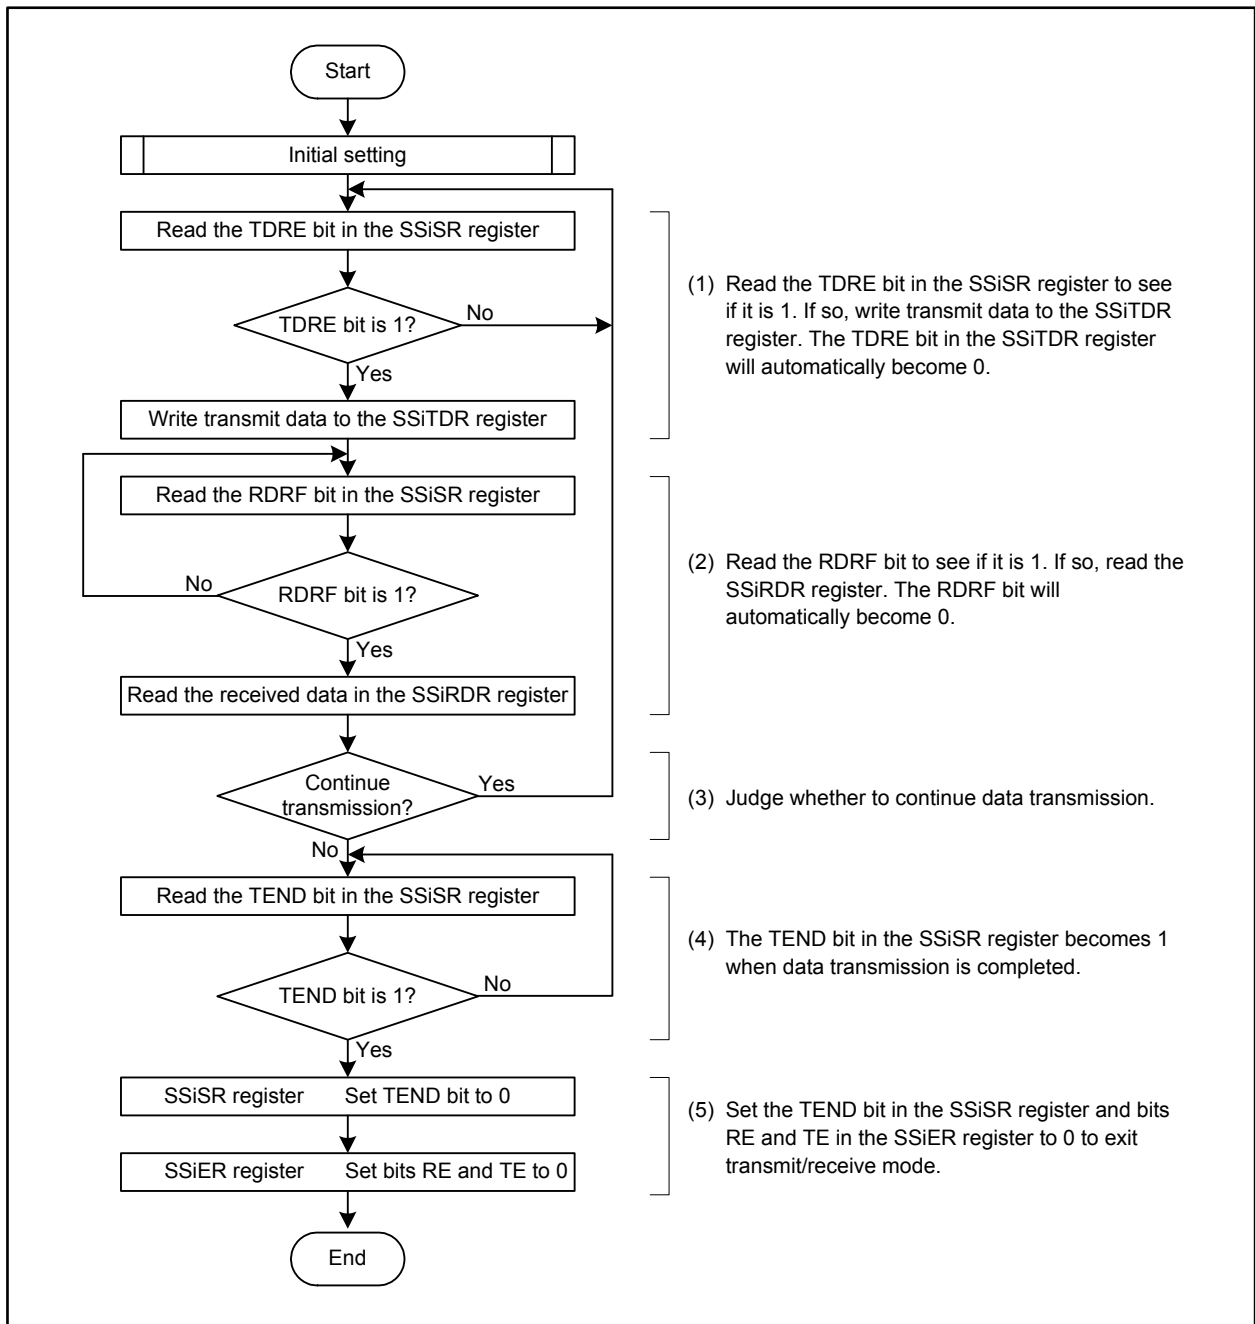

Figure 23.20 Data Transmission/Reception Example in Synchronous Communication Mode (i = 0 to 2)

23.1.7   4-wire Serial Bus Mode

In 4-wire serial bus mode, the serial bus interface operates serial communication via four logic signal lines: clock line, data input line, data output line, and chip select line. This mode also contains bidirectional mode, in which a single pin is used for the data input line and data output line.

The data input line and data output line share the SSIi pin and SSOi pin. The combined setting of the MSS bit in the SSiCRH register and the BIDE bit in the SSiMR2 register determines which line is assigned to which pin. Refer to 23.1.3 "Data I/O Pin and SSi Shift Register" for more details. In this mode, the clock polarity and phase for transmit/receive data can be configured by setting bits CPOS and CPHS in the SSiMR register, respectively. Refer to 23.1.1.1 "Transmit/Receive Clock Polarity and Phase" for more details.

The chip select line functions as an output pin in master mode and as an input pin in slave mode. In master mode, the $\overline{\text{SCSi}}$ pin can be assigned as an output pin by setting bits CSS1 and CSS0 in the SSiMR2 register to 10b. Also, a programmable I/O port can be assigned as the chip select pin in this mode. In slave mode, the $\overline{\text{SCSi}}$ pin is assigned as an input pin by setting bits CSS1 and CSS0 to 01b.

In 4-wire serial bus mode, serial communication is normally performed with the MSB first (the MLS bit in the SSiMR register is set to 0).

23.1.7.1   Initialization of 4-wire Serial Bus Mode

Figure 23.21 shows the initialization of 4-wire serial bus mode. Initialize the circuit by setting the TE bit in the SSiER register to 0 (transmission disabled) and the RE bit in the SSiER register to 0 (reception disabled) before a data transmission/reception.

To change the communication mode or the communication data format, set bits TE and RE to 0 in advance. Note that bits RDRF and ORER and the SSiRDR register are unaffected even if the RE bit is set to 0.
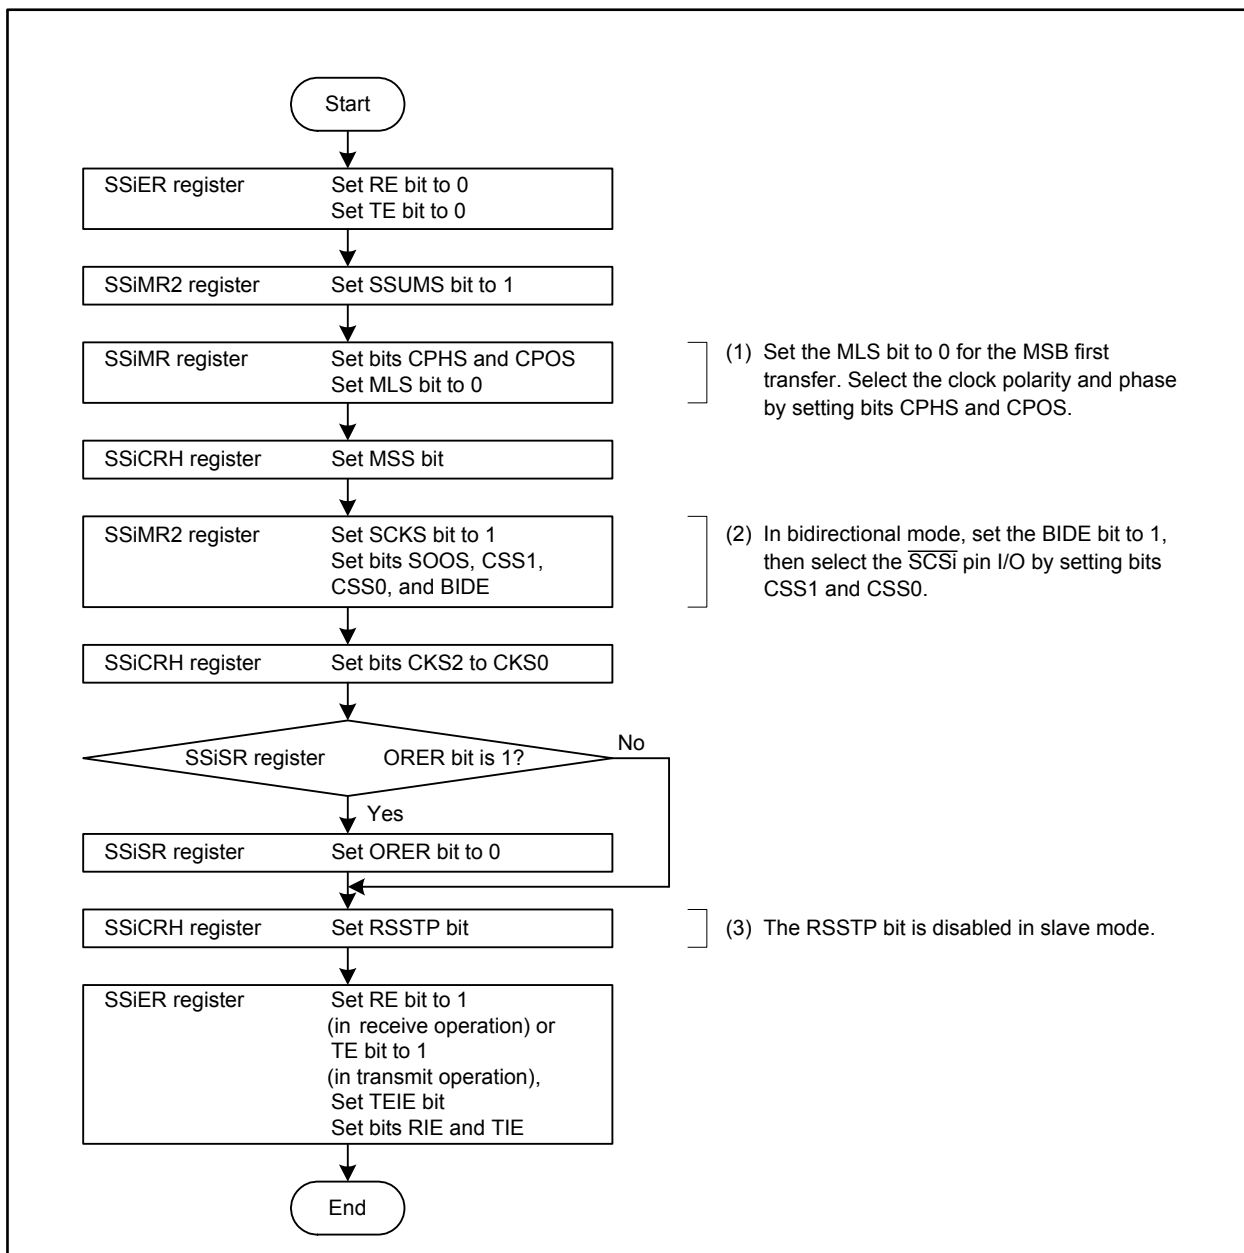

Figure 23.21 Initialization in 4-wire Serial Bus Mode (i = 0 to 2)

23.1.7.2   Data Transmission

Figure 23.22 shows an example of the transmit operation in 4-wire serial bus mode. During data transmission, the serial bus interface operates as described below.

When operating in master mode, an internally generated clock as a transmit/receive clock is output from the SSCKi pin. When operating in slave mode, the transmit/receive clock is a clock input from the SSCKi pin while the $\overline{SCSi}$ pin is low. In both cases, transmit data is output synchronized with the transmit/receive clock.

After setting the TE bit in the SSiER register to 1 (transmission enabled), if transmit data is written to the SSiTDR register, the TDRE bit in the SSiSR register automatically becomes 0 (unsent data left in the SSiTDR register), and data in the SSiTDR register is transferred to the transmit/receive shift register. Then the TDRE bit becomes 1 (no data left in the SSiTDR register) and data transmission starts. And, if the TIE bit in the SSiER register is 1 (transmit data register empty interrupt enabled), a transmit data empty interrupt request (TXI) is generated.

When the TDRE bit is 0, after transmitting one frame of data, the data is transferred from the SSiTDR register to the transmit/receive shift register to start the next data transmission. When the TDRE bit is 1, after transmitting the last bit of data, the TEND bit in the SSiSR register becomes 1 (transmission completed). And, if the TEIE bit in the SSiER register is 1 (transmit end interrupt enabled), a transmit end interrupt request (TEI) is generated.

After the data transmission is completed, the SSCKi pin and the $\overline{SCSi}$ pin become high. To continue data transmission with the $\overline{SCSi}$ pin low, write the data to be transmitted next to the SSiTDR register before the last bit is transmitted.

Note that data cannot be transmitted while the ORER bit in the SSiSR register is 1 (overrun error occurred). Set the ORER bit to 0 before data transmission.

In contrast to synchronous serial communication mode, the $\overline{SCSi}$ pin is used in 4-wire serial bus mode. When the serial bus interface is in master mode, the SSOi pin is high-impedance while the output level at the $\overline{SCSi}$ pin is high. In slave mode, the SSIi pin is high-impedance while the input level at the $\overline{SCSi}$ pin is high.

Refer to Figure 23.17 for an example of data transmission procedure.

(A) When the CPHS bit is 0 (change data at odd edges and load data at even edges)
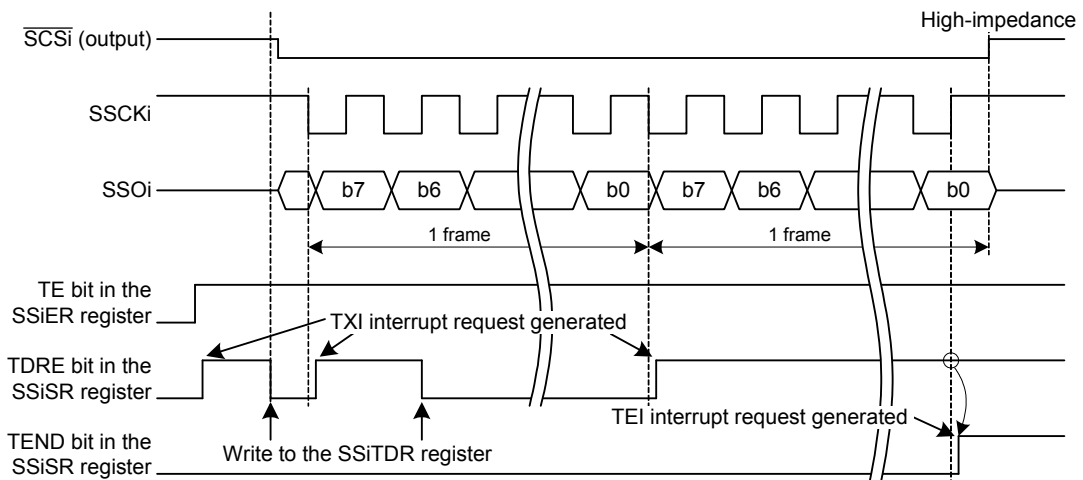

(B) When the CPHS bit is 1 (change data at even edges and load data at odd edges)
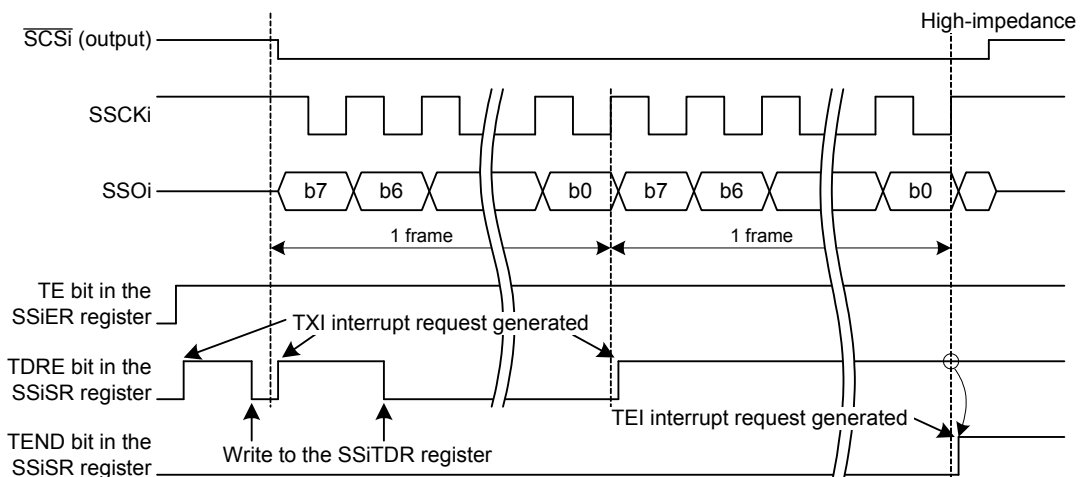

CPOS: Bit in the SSiMR register

Note:
  1. This figure applies under the following conditions:
        - The MSS bit in the SSiCRH register is 1 (master mode).
        - The CPOS bit in the SSiMR register is 0 (high when clock is stopped).
        - The MLS bit in the SSiMR register is 0 (MSB first).
        - Bits BC3 to BC0 are 1000b (8-bit length).
        - The CSOS bit in the SSiMR2 is 1 (SCSi pin is N-channel open drain output).

Figure 23.22 Transmit Operation Example in 4-wire Serial Bus Mode (i = 0 to 2)

23.1.7.3   Data Reception

Figure 23.23 shows an example of receive operation in 4-wire serial bus mode. During data reception, the serial bus interface operates as described below.

When operating in master mode, an internally generated clock as a transmit/receive clock is output from the SSCKi pin. When operating in slave mode, the transmit/receive clock is a clock input from the SSCKi pin while the $\overline{SCSi}$ pin is low. In both cases, receive data is input synchronized with the transmit/receive clock.

In master mode, a dummy read of the SSiRDR register evokes the receive clock output to start data reception. Note that the TE bit in the SSiER register should be set to 0 before performing the dummy read to exit transmit mode.

When the specified data length is received, the RDRF bit in the SSiSR register becomes 1 (received data left in the SSiRDR register) and the received data is stored into the SSiRDR register. And, if the RIE bit in the SSiER register is 1 (receive data register full interrupt/overrun error interrupt enabled), a receive data register full interrupt request (RXI) is generated. When the SSiRDR register is read, the RDRF bit automatically becomes 0 (no data left in the SSiRDR register).

To end the receive data operation in master mode, set the RSSTP bit in the SSiCRH register to 1 (receive operation ended after receiving the current frame) before reading the data of the second to last frame from the SSiRDR register. Then the transmit/receive clock stops when the last frame is received. When the clock stops, set the RE bit in the SSiER register to 0 (reception disabled) and the RSSTP bit to 0 (receive operation continued after receiving the current frame) and read the data of the last frame. Note that if the SSiRDR register is read while the RE bit is 1, then the receive clock is output again.

If the last bit of the data is received when the RDRF bit is 1, the ORER bit in the SSiSR register becomes 1 (overrun error occurred), and the receive operation stops. Note that data cannot be received while the ORER bit is 1. Set the ORER bit to 0 before resuming data reception.

Refer to Figure 23.19 for an example of data reception procedure.

(A) When the CPHS bit is 0 (change data at odd edges and load data at even edges)
(B) When the CPHS bit is 1 (change data at even edges and load data at odd edges)
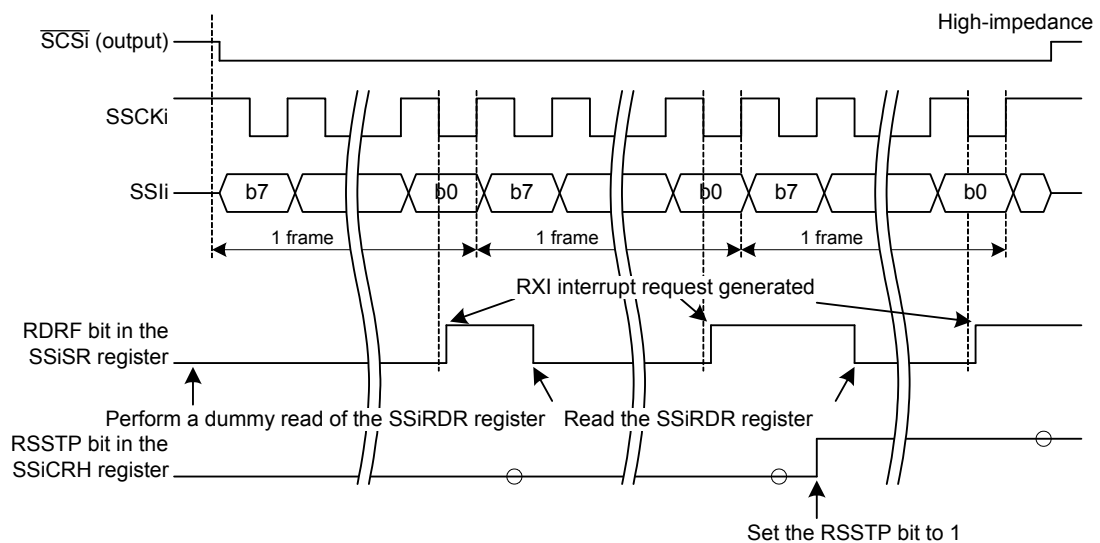

CPOS: Bit in the SSiMR register

Note:
1. This figure applies under the following conditions:
   - The MSS bit in the SSiCRH register is 1 (master mode).
   - The CPOS bit in the SSiMR register is 0 (high when clock is stopped).
   - The MLS bit in the SSiMR register is 0 (MSB first).
   - Bits BC3 to BC0 in the SSiMR register is 1000b (8-bit length).
   - The CSOS bit in the SSiMR2 register is 1 (SCSi is N-channel open drain output).

Figure 23.23 Receive Operation Example in 4-wire Serial Bus Mode (i = 0 to 2)

23.1.7.4 $\overline{\text{SCSi}}$ Pin Control and Arbitration

In 4-wire serial bus mode, when bits CSS1 and CSS0 are set to 10b (functions as $\overline{\text{SCSi}}$ output pin), and the MSS bit in the SSiCRH register is 1 (master mode), then arbitration is performed by monitoring the $\overline{\text{SCSi}}$ pin before starting serial data transmission. When the serial bus interface detects that the synchronized internal $\overline{\text{SCSi}}$ signal level drops to low before data transmission, the CE bit in the SSiSR register becomes 1 (conflict error occurred) and the MSS bit automatically becomes 0 (slave mode). Figure 23.24 shows the arbitration timing.

Note that the serial bus interface can no longer continue transmitting while the CE bit is 1. To start data transmission, confirm the CE bit is 1 and then set it to 0 (no conflict error).
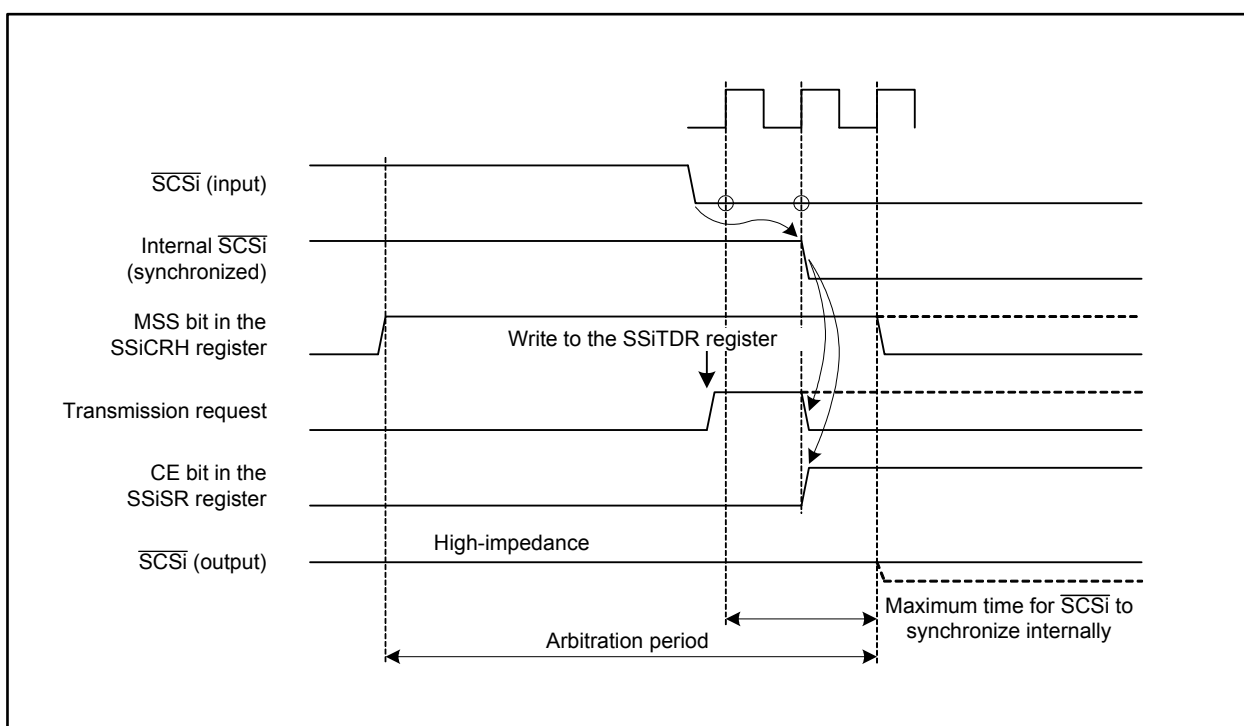

Figure 23.24 Arbitration Timing (i = 0 to 2)

23.2   Note on Serial Bus Interface

23.2.1   Note on Synchronous Serial Communication Mode and 4-wire Serial Bus Mode

23.2.1.1   Accessing SBI Associated Registers

To read the SBI associated registers (44F06h to 44F2Fh), insert at least three instructions after writing to the registers.

  • An example of inserting at least three instructions
      Program example   MOV.B   #00h, 44F0Bh ; Set the SS0ER register to 00h.
                               NOP
                               NOP
                               NOP
                               MOV.B   44F0Bh, R0L

24. LIN Module

The R32C/156 Group implements a local interconnect network (LIN) module, compliant with LIN Protocol Specification Revisions 1.3, 2.0, and 2.1, which transmits and receives frames, and judges errors automatically. The module incorporates four channels of master controllers.
Table 24.1 lists the LIN module specifications and Figure 24.1 shows the LIN module block diagram.

Table 24.1   LIN Module Specifications

Item	Specification
Protocols	LIN Protocol Specification Revisions 1.3, 2.0, and 2.1
Channels	4 (LIN master)

Variable frame composition	Transmit break length: 13 to 28 Tbit
	Transmit break delimiter length: 1 to 4 Tbit
	Interbyte space (Header): 0 to 7 Tbit
	  (space between Sync field and ID field) [1]
	Response space: 0 to 7 Tbit [1]
	Interbyte space: 0 to 3 Tbit
	  (space between bytes in response space)

Checksum	Classic checksum or enhanced checksum selectable (changeable at each channel and each frame)
Data byte(s) in response field	Variable from 0 to 8
Frame transmission modes	Non-frame separate mode or frame separate mode selectable; the former mode transmits a header and response by a single start command and the latter separately transmits them by respective start command

Wake-up transmission/reception	Available in LIN wake-up mode
	• Wake-up transmission (1 to 16 Tbit)
	• Wake-up reception
	  • Input signal low time count (0.5 to 15.5 Tbit)
	  • Input signal low detection

Operational status	• Frame/wake-up transmit completion • Frame/wake-up receive completion • Data 1 receive completion • Input signal low detection • Error detection • Operating mode
Error status	• Bit error • Checksum error • Frame timeout error • Physical bus error • Framing error • Overrun error Excluding the checksum error, these errors are detection enable or detection disable selectable
Baud rates	The baud rate generator can generate the baud rates in the LIN specifications (each channel can be selected separately)

Note:
  1.   The interbyte space (Header) has the same value as the response space since both spaces are set in the same register.
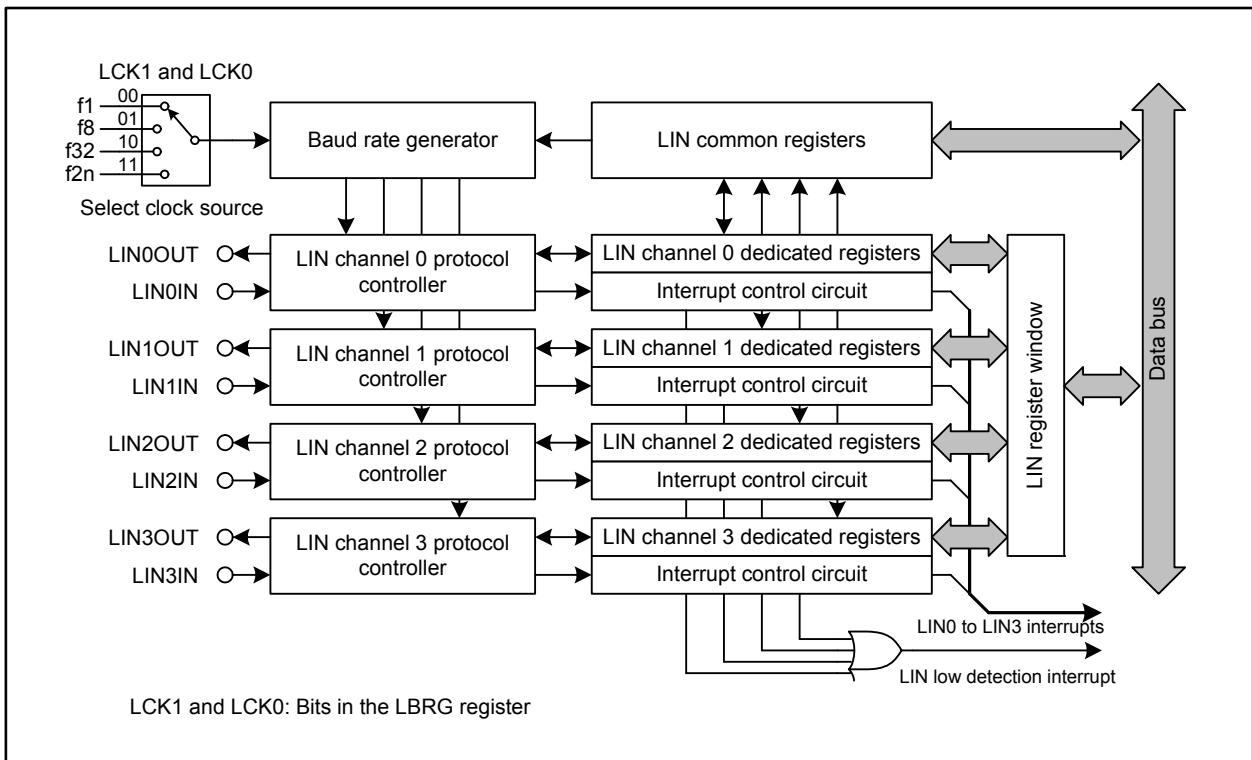

Figure 24.1   LIN Module Block Diagram

• LINjOUT, LINjIN (j = 0 to 3): LIN I/O pins
• Baud rate generator: Generates a communication clock for LIN
• LIN common registers: Common registers for the LIN module
• LIN channel j dedicated registers:
    A set of dedicated registers for each channel. Each set of registers can be used by switching the
    register window using the LCW register.
• Interrupt control circuit:
    Controls the interrupt requests (LINj interrupt and LIN low detection interrupt) generated by the LIN
    module

24.1   LIN Module Associated Registers

The LIN module has two types of registers: LIN module common registers and LIN channel dedicated registers.

The latter compose up to four register banks for channels 0 to 3, of which an appropriate register bank is selected by switching a channel to be shown on the window. The number of channels per module depends on total channels incorporated.

24.1.1   LIN Common Registers

• LIN channel window select/input signal low detection status register (LCW register)
This register is to select a channel and monitor the status of input signal low detection of each channel.
• LIN baud rate generator control register (LBRG register)
This register is to select a count source for the baud rate generator and fLn clock source. Refer to 24.4 "Baud Rate Generator" for details.
• LIN baud rate prescaler k (LBRPk register) (k = 0, 1)
This register is to set the division value for the baud rate prescaler to generate a transmit/receive clock with the count source selected by the LBRG register.

24.1.2   LIN Channel Dedicated Registers

Select a channel by setting bits CWS1 and CWS0 in the LCW register. Each LIN channel dedicated register of the selected channel can be set via the following registers:
• LIN mode register 0 (LMD0 register)
This register is used for the initial setting of LIN module including mode selections and interrupt enable settings.
• LIN mode register 1 (LMD1 register)
This register is used for the initial setting of LIN module including system clock selection and error detection enable settings.
• LIN wake-up setting register (LWUP register)
This register sets the low time pulse width of wake-up transmission and reception.
• LIN break field setting register (LBRK register)
This register sets the transmit break length and transmit break delimiter length in break field.
• LIN space setting register (LSPC register)
This register sets each space width required for transmission.
• LIN response field setting register (LRFC register)
This register sets the number of communication data bytes, the transmit/receive direction, and a checksum model.
• LIN ID buffer register (LIDB register)
This register sets the transmission ID and ID parity bits.
• LIN status control register (LSC register)
This register changes the LIN operating mode.
• LIN transmission control register (LTC register)
This register sets to start the frame/wake-up transmission and response field transmission.
• LIN status register (LST register)
This register monitors the status including frame/wake-up transmit completion, frame/wake-up receive completion, Data 1 receive completion, input signal low detection, error detection, and operating mode.
• LIN error status register (LEST register)
This register monitors error status caused by bit, checksum, physical bus, frame timeout, framing, and overrun errors).
• LIN data n buffer register (LDBn register) (n = 1 to 8)
This register, commonly used as transmission and reception data buffer, sets data to be transmitted and to read received data.

24.1.3 Register Window and Channel Switching

The LIN channel dedicated registers, which are not directly mapped on the memory map of the CPU, are accessed via a register window. The register window is mapped at addresses 44E04h to 44E17h. According to the setting of bits CWS1 and CWS0 in the LCW register, the LIN channel dedicated registers of the corresponding channel are collectively mapped on the register window.
Figure 24.2 shows the block diagram of the register window.

Figure 24.2 Register Window

Figures 24.3 to 24.18 show LIN module associated registers.

1. Set this register under the following conditions:
    - The RFT bit in the LRFC register of the corresponding channel is 1 (transmission).
    - The FSM bit in the LMD0 register of the corresponding channel is 0 (non-frame separate mode).
    - The FTS bit in the LTC register of the corresponding channel is 0 (stop frame/wake-up transmission).
    or
    - The RFT bit of the corresponding channel is 1 (transmission).
    - The FSM bit of the corresponding channel is 1 (frame separate mode).
    - The RTS bit in the LTC register of the corresponding channel is 0 (stop response transmission).

Figure 24.18 Registers LDB1 to LDB8

24.2 Operating Modes

The LIN modules have the following three operating modes:
- LIN reset mode
- LIN operating mode
- LIN wake-up mode

Entering operation modes is controlled for each channel. When all channels are in LIN reset mode, power consumption is reduced since the clock is not provided to the LIN module. Figure 24.19 shows the transition processes between LIN operating modes and Table 24.2 lists functions available in each mode.
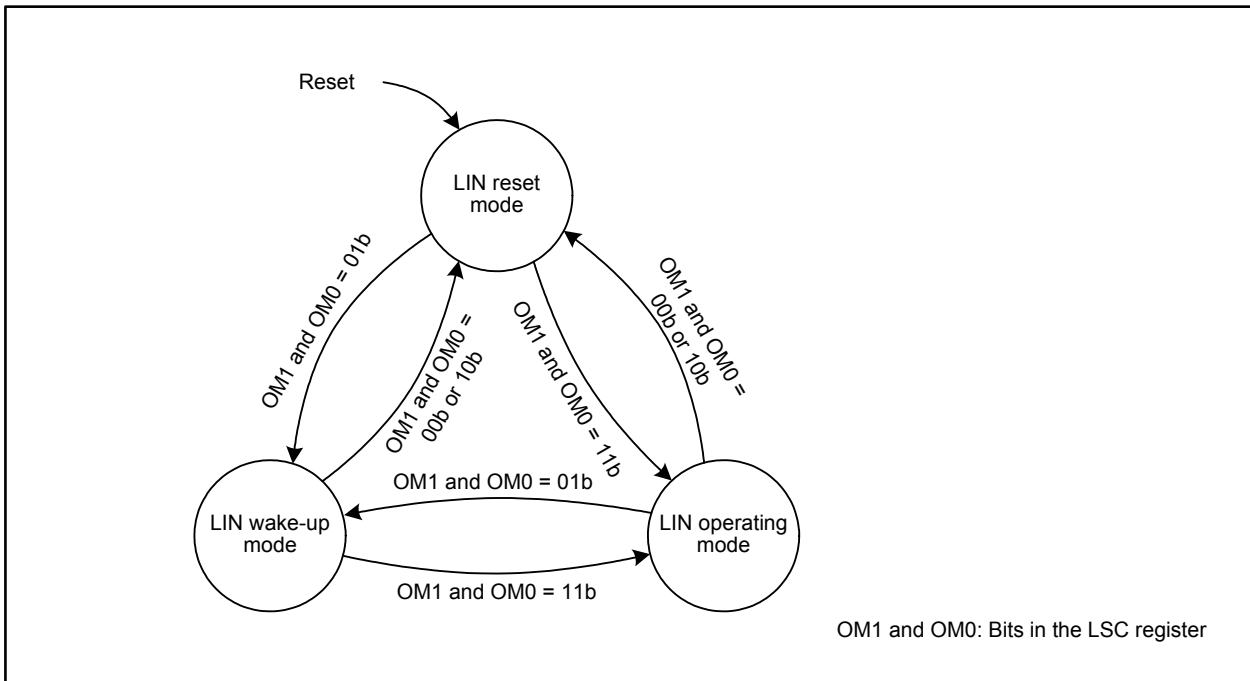

Figure 24.19 LIN Operating Mode Transition

Table 24.2   Functions Available in Each Operating Mode

LIN Reset Mode	LIN Operating Mode	LIN Wake-up Mode
Input signal low detection	Header transmission Response transmission Response reception Error detection Input signal low detection	Wake-up transmission Wake-up reception Error detection Input signal low detection

Read bits OMM1 and OMM0 in the LST register of the corresponding channel to verify that the LIN module has entered each operating mode.
Note that bits OM1 and OM0 and bits OMM1 and OMM0 are allocated differently in each operating mode.

24.2.1   LIN Reset Mode

When bits OM1 and OM0 in the LSC register of the corresponding channel are set to 00b or 10b, the selected LIN channel enters LIN reset mode, and bits OMM1 and OMM0 in the LST register become 00b or 01b. In this mode, all LIN functions of the corresponding channel are stopped as well as the clock supply to the LIN module (fLIN) of the channel.

24.2.2   LIN Operating Mode

When bits OM1 and OM0 in the LSC register of the corresponding channel are set to 11b, the selected LIN channel enters LIN operating mode, and bits OMM1 and OMM0 in the LST register become 11b.

24.2.3   LIN Wake-up Mode

When bits OM1 and OM0 in the LSC register of the corresponding channel are set to 01b, the selected LIN channel enters LIN wake-up mode, and bits OMM1 and OMM0 in the LST register become 10b.

24.3   Operational Overview

24.3.1   Header Transmission

Figure 24.20 shows the operation in header transmission and Table 24.3 lists the processing in header transmission.
Figure 24.20 Operation in Header Transmission

Table 24.3   Processing in Header Transmission

		Software Processing	LIN Module Processing

(1)		• Set a baud rate
		• Set the following bits in the LMD0 register:
		  The FTCIE bit to 1 (frame/wake-up transmit completion interrupt enabled);
		  The FRCIE bit to 1 (frame/wake-up receive completion interrupt enabled);
		  The ERRIE bit to 1 (error detection interrupt enabled)
		• Change the operating mode of the corresponding LIN channel
		• Set the following bits in the LBRK register:
		  Bits BLT3 to BLT0 for break low (13 to 28 Tbit);
		  Bits BDT1 and BDT0 for break delimiter (1 to 4 Tbit)
		• Set the following bits in the LSPC register:
		  Bits IBSH2 to IBSH0 for interbyte space (Header)/response space (0 to 7 Tbit);
		  Bits IBS1 and IBS0 for interbyte space (0 to 3 Tbit)
		• Set the following bits in the LIDB register:
		  Bits ID5 to ID0 for ID value;
		  Bits IDP1 and IDP0 for parity value
		• Set the following bits in the LRFC register:
		  Bits RFDL3 to FRDL0 for data length;
		  The RFT bit for response transmit/receive direction
		  The CSM bit for checksum model
		• Set the transmit data
			Wait for frame/wake-up transmission start by software (idle)

(2)		• Set the FTS bit in the LTC register to 1 (frame/wake-up transmission started)	Transmit break
(3)		• Wait for an interrupt request to be generated	Transmit break delimiter
(4)			Transmit Sync field (55h)
(5)			Transmit interbyte space (Header)
(6)			Transmit ID field
(7)			Transmit response space

24.3.2   Response Transmission

Figure 24.21 shows the operation in response transmission and Table 24.4 lists the processing in response transmission.
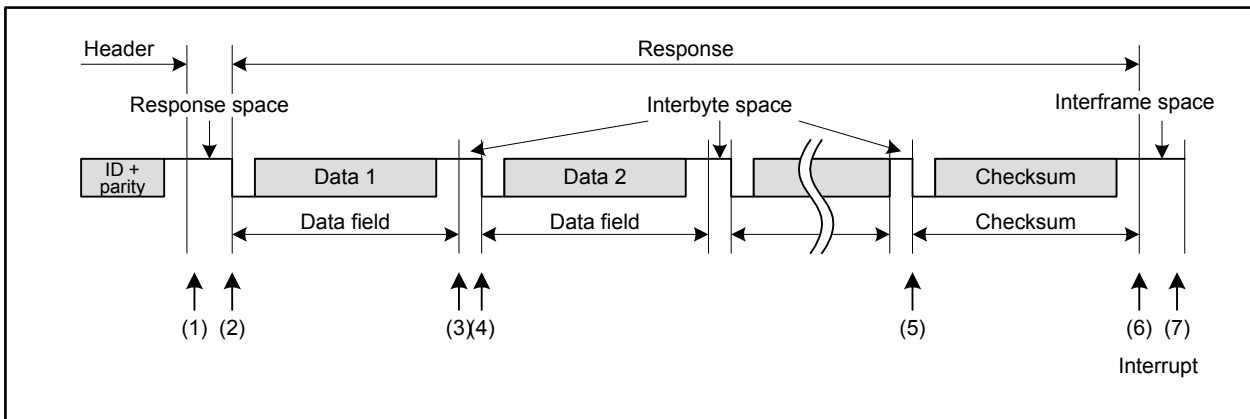

Figure 24.21 Operation in Response Transmission

Table 24.4   Processing in Response Transmission

	Software Processing	LIN Module Processing

(1)	• In frame separate mode
	  Set the RTS bit in the LTC register to 1 (response transmission started)
	• In non-frame separate mode
	  Wait for an interrupt request to be generated
		• In frame separate mode
		  Transmit response space while waiting for response transmission enabled
		• In non-frame separate mode
		  Go to (2) if the response space transmission is completed

(2)	Wait for an interrupt request to be generated	Transmit Data 1
(3)		Transmit interbyte space
(4)		Transmit Data 2, then the next interbyte space Transmit Data 3, then the next interbyte space (Repeat this process for the data length specified in bits RFDL3 to RFDL0 in the LRFC register. Go to (6) if an error occurs.)
(5)		Transmit checksum

(6)		• Set frame/wake-up transmit completion flag or error flag
		• Set the following bits in the LTC register:
		  The FTS bit to 0 (frame/wake-up transmission stopped);
		  The RTS bit to 0 (response transmission stopped)

(7)	• Processing after communication Check the LST register and set flags to 0	Idle

24.3.3 Response Reception

Figure 24.22 shows the operation in response reception and Table 24.5 lists the processing in response reception.
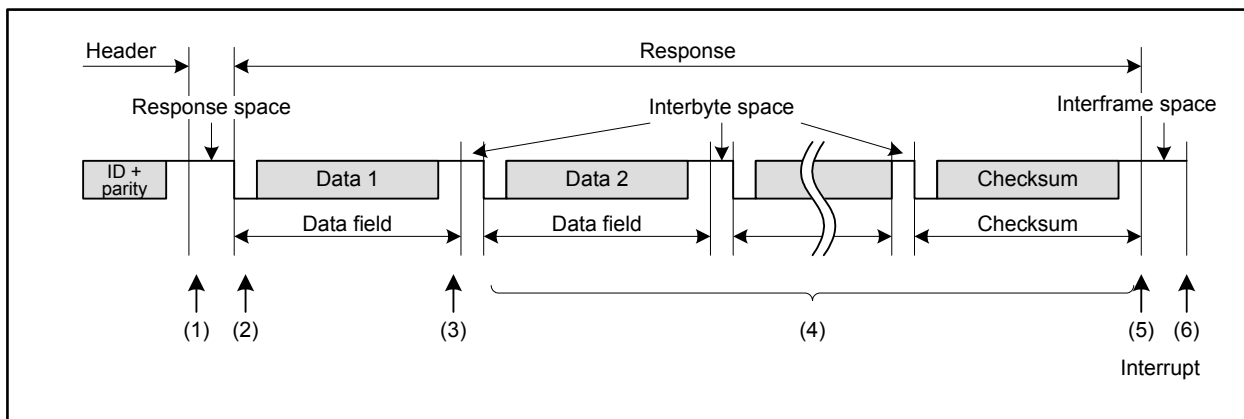

Figure 24.22 Operation in Response Reception

Table 24.5   Processing in Response Reception

	Software Processing	LIN Module Processing
(1)	Wait for an interrupt request to be generated (without processing)	Wait for a start bit to be detected
(2)	Wait for an interrupt request to be generated	Receive Data 1 due to start bit detection
(3)		• Set Data 1 receive completion flag
(4)		Receive Data 2 due to start bit detection Receive Data 3 due to start bit detection (Repeat this process for the data length specified in bits RFDL3 to RFDL0 in the LRFC register. Abort the reception and go to (5) if an error occurs. Checksum judgement is not performed in this case.) : : : Receive checksum due to start bit detection
(5)		• Judge the checksum • Set frame receive completion flag or error flag • Set the FTS bit in the LTC register to 0 (frame/wake-up transmission stopped)
(6)	Processing after communication Check the LST register and set flags to 0	Idle

24.4   Baud Rate Generator

The LIN module system clock (fLIN) is generated by peripheral clock divided by the baud rate generator. The fLIN divided by 8 or 16 is used as the bit rate. The reciprocal of the bit rate is called bit time and expressed as "Tbit".

When the BTD bit in the LMD0 register is 0 (1 Tbit is generated by 8 fLIN), the FLNS bit in registers LBRG and LBRP0 should be set so that fLn is 153600 Hz (19200 bps × 8). Therefore,

fLn = 19200 bps × 8 [Hz]

fLn2 = 9600 bps × 8 [Hz]

fLn8 = 2400 bps × 8 [Hz]

Then they are divided by 8 in the bit timing generator, which results in 19200 bps, 9600 bps, and 2400 bps, respectively. The baud rate of 10417 bps is generated by the bit setting in the LBRP1 register.

When the BTD bit is 1 (1 Tbit is generated by 16 fLIN), the FLNS bit in registers LBRG and LBRP0 should be set so fLn is 307200 Hz (= 19200 bps × 16).

Figure 24.23 shows the block diagram of baud rate generation.

Notes:
    1. Divide-by-(n+1) is set by the LBRP0 register (n = 1 to 255).
    2. Divide-by-(m+1) is set by the LBRP1 register (m = 1 to 255).
    3. Set fLIN to a frequency lower than the peripheral bus clock divided by 2.

fLIN: LIN module system clock
LCK1, LCK0, and FLNS: Bits in the LBRG register
BTD: Bit in the LMD0 register
CKS2 to CKS0: Bits in the LMD1 register
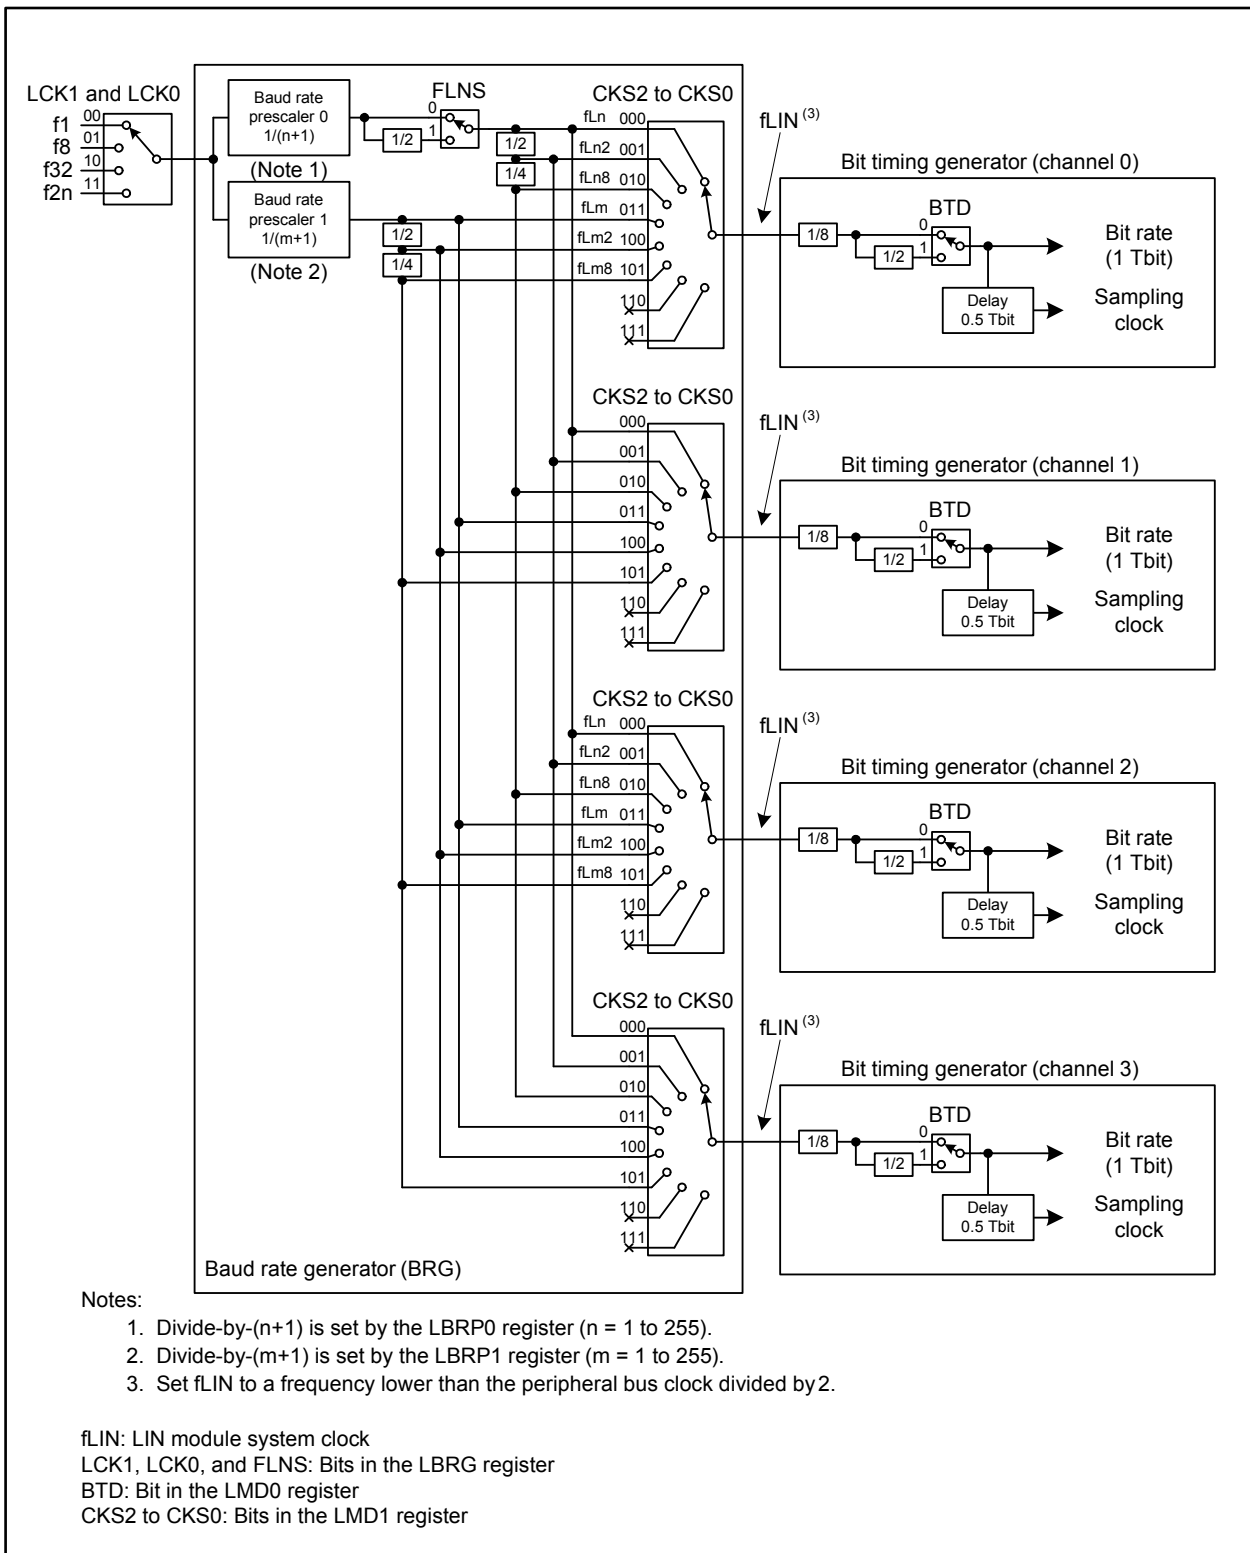

Figure 24.23 Baud Rate Generation Block Diagram

Tables 24.6 and 24.7 list the baud rates (19200, 9600, 2400, and 10417 bps) generated by the peripheral clock frequency, and their errors.

Table 24.6   Baud Rate Generation Example (for 19200, 9600, and 2400 bps)

Peripheral Clock	Divide-by-(n + 1)	BRP0 Output	Bit Times	fLn [19200 bps] (unit: bps)	fL2n [9600 bps] (unit: bps)	fL8n [2400 bps] (unit: bps)	Error (unit: %)
32 MHz	104	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
30 MHz	98	No division/ divide-by-2	16 fLIN/ 8 fLIN	19132.65	9566.33	2391.58	-0.35
24 MHz	78	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
20 MHz	65	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
16 MHz	52	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
12 MHz	39	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
10 MHz	65	No division [1]	8 fLIN	19230.77	9615.38	2403.85	+0.16
8 MHz	26	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
4 MHz	13	No division/ divide-by-2	16 fLIN/ 8 fLIN	19230.77	9615.38	2403.85	+0.16
2 MHz	13	No division [1]	8 fLIN	19230.77	9615.38	2403.85	+0.16

Note:
1.   An error does not fulfill the LIN protocol specification (±0.5%) if the BRP0 clock is divided by 2.

Table 24.7   Baud Rate Generation Example for 10417 bps

Peripheral Clock	Divide-by-(m + 1)	Bit Times	fLIN	Baud Rate [10417 bps] (unit: bps)	Error (unit:%)

2 MHz	3 / 6	8 fLIN / 16 fLIN	fLm8 / fLm2	10416.67	-0.003

24.5 Data Transmission and Reception

24.5.1 Data Transmission

The LIN module transmits 1-bit data per Tbit.

The transmitted data returns to the input pin for data reception via the LIN transceiver. Then the received data is compared to the transmitted data and the result is stored in the BER bit in the LEST register (refer to 24.10 "Error Status" for details). The timing to compare the received data is at the fifth clock when the BTD bit in the LMD0 register is 0 (1 Tbit is generated by 8 fLIN), and at the 13th clock when the BTD bit is 1 (1 Tbit is generated by 16 fLIN).

Figure 24.24 shows data transmission timing.

Figure 24.24 Data Transmission Timing (j = 0 to 3)

24.5.2   Data Reception

Data reception in the LIN module requires an internal signal generated from the input signal at the LINjIN (j = 0 to 3) pin by a double-latch clocking scheme.

The byte field of this internal signal, called the synchronized LINjIN, is synchronized with fLIN at the falling edge of the start bit. The synchronized LINjIN signal is sampled again 0.5 Tbit after a falling edge is detected, and if the signal is low, it is verified as the start bit. It is not verified as the start bit if the LINjIN signal has been low after a reset is released or high is detected on sampling.

Once the start bit is detected, data bits are sampled every Tbit.

Figure 24.25 shows the data reception timing.
Figure 24.25 Data Reception Timing (j = 0 to 3)

24.6 Buffer Processing of Transmit/Receive Data

This section describes buffer processing when the LIN module is continuously transmitting and receiving data.

24.6.1 Transmission of LIN Frame

In 8-byte transmission, the values stored in registers LDB1 to LDB8 of each channel are transmitted in order to Data 1 to Data 8 of the LIN frame.

In 4-byte transmission, the values stored in registers LDB1 to LDB4 are transmitted to Data 1 to Data 4 of the LIN frame, and the values stored in registers LDB5 to LDB8 are not transmitted.

Figure 24.26 shows the processing of LIN transmission and buffer.
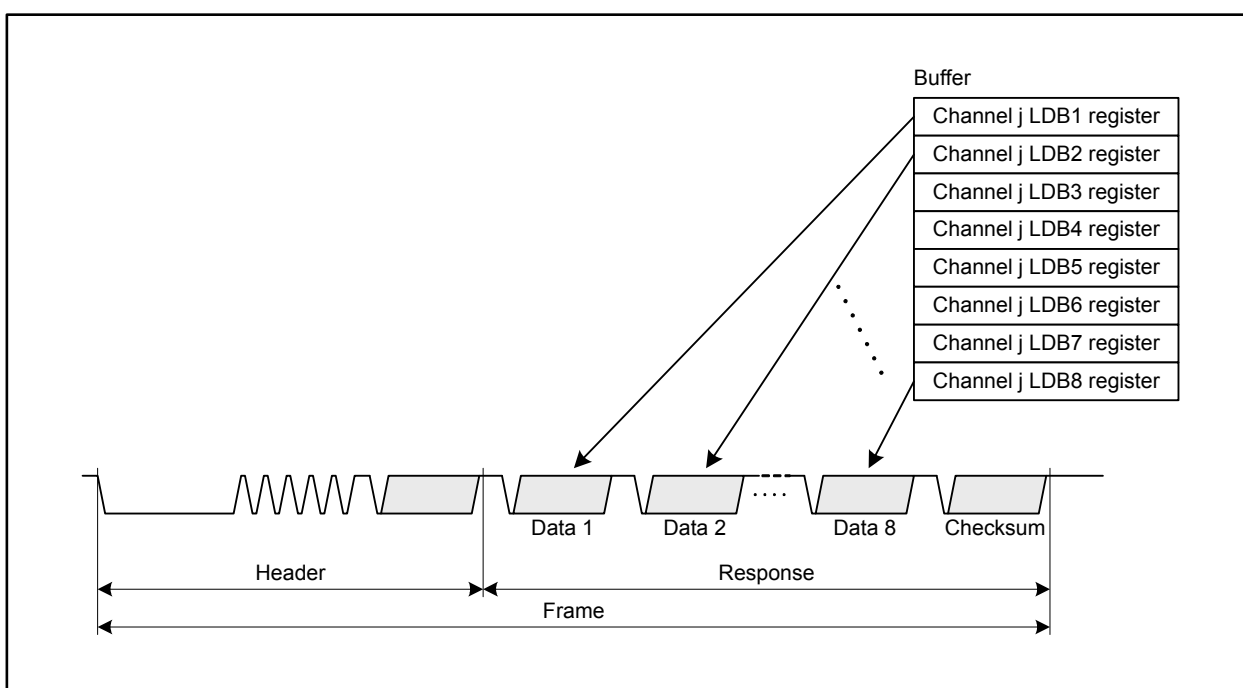

Figure 24.26 Processing of LIN Transmission and Buffer (j = 0 to 3)

24.6.2   Reception of LIN Frame

In 8-byte reception, the values of Data 1 to Data 8 of the LIN frame are stored in registers LDB1 to LDB8 of each channel in order at every completion of stop bit reception. In 4-byte reception, the values of Data 1 to Data 4 of the LIN frame are stored in registers LDB1 to LDB4 respectively, and no bits are stored in registers LDB5 to LDB8.

Figure 24.27 shows the processing of LIN reception and buffer.
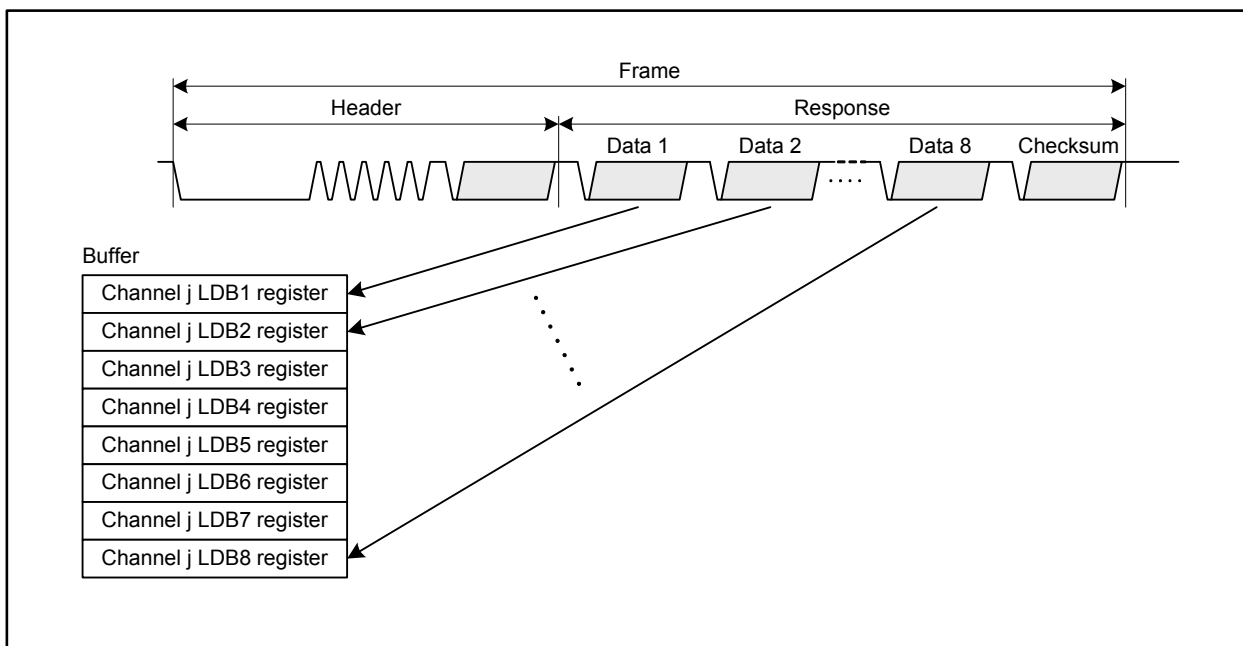

Figure 24.27 Processing of LIN Reception and Buffer (j = 0 to 3)

24.7   Wake-up Transmission and Reception

Wake-up transmission and reception can be used in LIN wake-up mode.

24.7.1   Wake-up Transmission

24.7.1.1   Operation of Wake-up Transmission

In LIN wake-up mode, when the FTS bit in the LTC register is set to 1 (frame/wake-up transmission started), the wake-up signal is output at the output pin of the selected channel. Low time pulse width of the wake-up signal is set by bits WUTL3 to WUTL0 in the LWUP register.

When low of wake-up is output without any bit error detected, the FTC bit in the LST register becomes 1 (frame/wake-up transmission completed). When the FTCIE bit in the LMD0 register is 1 (frame/wake-up transmit completion interrupt enabled), an interrupt request is generated.

When a bit error is detected, the operation is aborted and the BER bit in the LEST register becomes 1 (bit error is detected).

Figure 24.28 shows the wake-up transmission timing.

LINjOUT

Low time setting (1 to 16 Tbit)

FTC bit in the LST register
Figure 24.28 Wake-up Transmission Timing (j = 0 to 3)

24.7.1.2   Wake-up Collision

When the master and slave transmit wake-up signals simultaneously, a signal collision occurs on the LIN bus. However, no collision of the wake-up signals is detected in the LIN module.

Even if the LIN bus is fixed low, it is not recognized as a wake-up signal: the input signal low time count does not function unless a recessive (high) is detected once after the wake-up signals are transmitted.

24.7.2   Wake-up Reception

24.7.2.1   Wake-up Reception Operation

A wake-up is detected by either of the following functions: input signal low time count or input signal low detection. The input signal low time count is available in LIN wake-up mode and the input signal low detection is available in all LIN operating modes.

The input signal low time count measures the low time of an input signal at the LINjIN pin (j = 0 to 3) by counting at the same sampling timing as that of data reception. When the counted low time reaches the value set with bits WURL3 to WURL0 in the LWUP register, the FRC bit in the LST register becomes 1 (frame/wake-up reception completed). When the FRCIE bit in the LMD0 register is 1 (frame/wake-up receive completion interrupt enabled), an interrupt request is generated.

On the other hand, the input signal low detection is to asynchronously detect the falling edge of the input signal at the LINjIN pin. While the LDE bit in the LMD0 register is 1 (input signal low detection enabled), the LD bit in the LST register becomes 1 (input signal low detected) when the falling edge is detected, and an interrupt request is generated.

Figure 24.29 shows an example of the wake-up detection.
When the bit rate is 19200 bps (1 Tbit = 52 μs) and the pulse width is 3.5 Tbit (bits WURL3 to WURL0 is 0011b), the low time pulse over 182 μs (= 52 μs × 3.5) is recognized as the wake-up signal.
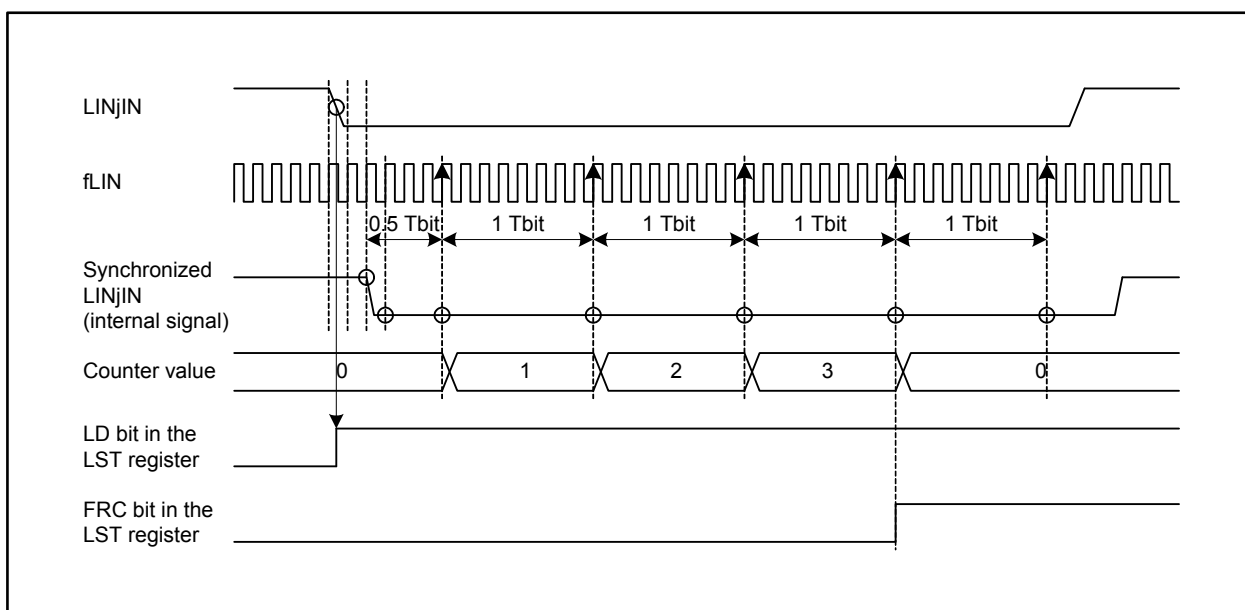

Figure 24.29 Wake-up Detection (j = 0 to 3)

The input signal low time count is not available during the wake-up transmission processing, however, the input signal low detection is. If the FTS bit in the LTC register is set to 1 (start frame/ wake-up transmission) while a wake-up reception is being counted, the reception processing is aborted to perform the wake-up transmission.

24.8   Low Power Mode Control Using Input Signal Low Detection

The input signal low detection can be used as the interrupt to exit wait mode or stop mode.
Figure 24.30 shows a setting example before entering wait mode. Refer to 7.7.2 "Wait Mode" and 7.7.3 "Stop Mode" for details on entering wait or stop mode.

```

Notes:
1. This flowchart shows an example of the setting procedure to exit wait mode using a wake-up signal from the LIN bus after entering wait mode.
2. Set the LIN module in PLL mode (high speed mode or medium speed mode).
3. The setting depends on the LIN transceiver specification.
4. Enter low speed mode or low power mode before setting the I flag to 1.

Figure 24.30 Example of Setting Before Transition to Wait Mode

24.9 Operational Status

The LIN module detects six types of operational statuses.

Statuses that can generate an interrupt request are: frame/wake-up transmit completion, frame/wake-up receive completion, input signal low detection, and error detection.

Table 24.8 lists the types of operational statuses.

Table 24.8   Operational Statuses (j = 0 to 3)

Operational Status	Detecting Condition	Detectable Operating Modes	Corresponding Bits in the LST Register
Frame/wake-up transmit completion	When a response frame transmission has been successfully completed in the bit setting as follows: RFT bit in the LRFC register is 1 (transmission selected)	LIN operating mode	FTC
	When a wake-up transmission has been successfully completed	LIN wake-up mode	
Frame/wake-up receive completion	When a response frame reception has been successfully completed in the bit setting as follows: RFT bit in the LRFC register is 0 (reception selected)	LIN operating mode	FRC
	When the low time of the input signal reaches the setting value of bits WURL3 to WURL0 in the LWUP register	LIN wake-up mode	
Input signal low detection	When the falling edge of the input signal at the LINjIN pin is detected with the setting of the LDE bit in the LMD0 register to 1 (input signal low detection enabled), or when setting the LDE bit to 1 while the LINjIN pin is low	All LIN modes	LD
Error detection	When any bit from 0 to 5 in the LEST register becomes 1 (error detected)	LIN operating mode LIN wake-up mode	ERR
Operating mode	When LIN module has entered the operating mode which was set by bits OM1 and OM0 in the LSC register	All LIN modes	OMM1 and OMM0
Data 1 receive completion	When the reception of the first byte of a response frame has been completed in the bit setting as follows: RFT bit in the LRFC register is 0 (reception selected) [1]	LIN operating mode	D1RC

Note:

1.   This status is detected except when bits RFDL3 to RFDL0 in the LRFC register are 0000b (0 bytes + checksum).

24.10 Error Status

24.10.1 Error Status Types

The LIN module detects six types of error statuses. These error statuses can be checked by bits 0 to 5 in the LEST register.
Table 24.9 lists the types of error statuses.

Table 24.9   Error Statuses

Error Status	Error Detecting Condition	Error Detectable Operating Mode	Communication Processing	Detection Enabled/ Disabled	Corresponding Bit in the LEST Register
Bit error	When the transmitted data does not match with that on the LIN bus monitored by the pin for reception	LIN operating mode LIN wake-up mode	Abort [1]	Selectable	BER
Physical bus error	When LIN bus has already become low just before the break field is transmitted or when it is detected that LIN bus is being fixed to high	LIN operating mode LIN wake-up mode	Abort	Selectable	PBER
Check sum error	When the checksum judgement of the response frame reception processing results in an error	LIN operating mode	—	Not selectable	CSER
Frame timeout error	When the transmit/receive operation is not completed within a specified period of time [2]	LIN operating mode	Abort	Selectable	FTER
Framing error	When the stop bit of each data byte is low in response frame reception processing	LIN operating mode	Abort	Selectable	FER
Overrun error	When the first data byte of the next response frame is received while the FRC bit in the LST register is 1 (frame reception successfully completed)	LIN operating mode	Abort	Selectable	OER

Notes:
1. When a bit error is detected, the processing is aborted after the stop bit is transmitted. If it is detected in a non-data space, such as an interbyte space, the transmission processing is aborted after a check in that space is completed. During wake-up transmission, the wake-up transmission is aborted immediately after the error bit is transmitted.
2. The period of time (as time out value) depends on the response field data length set by bits RFDL3 to RFDL0 in the LRFC register as follows:

$$\text{Time out value} = 50 + (\text{data bytes} + 1) \times 14 \qquad [\text{Tbit}]$$

The above period of time will exceed the value of T_{FRAME_MAX} ({(10 × data bytes + 44) + 1} × 1.4) shown in LIN Specification Package Revision 1.3.

24.10.2 LIN Error Detection Targets

Figure 24.31 shows the area which the LIN module monitors for error detection.
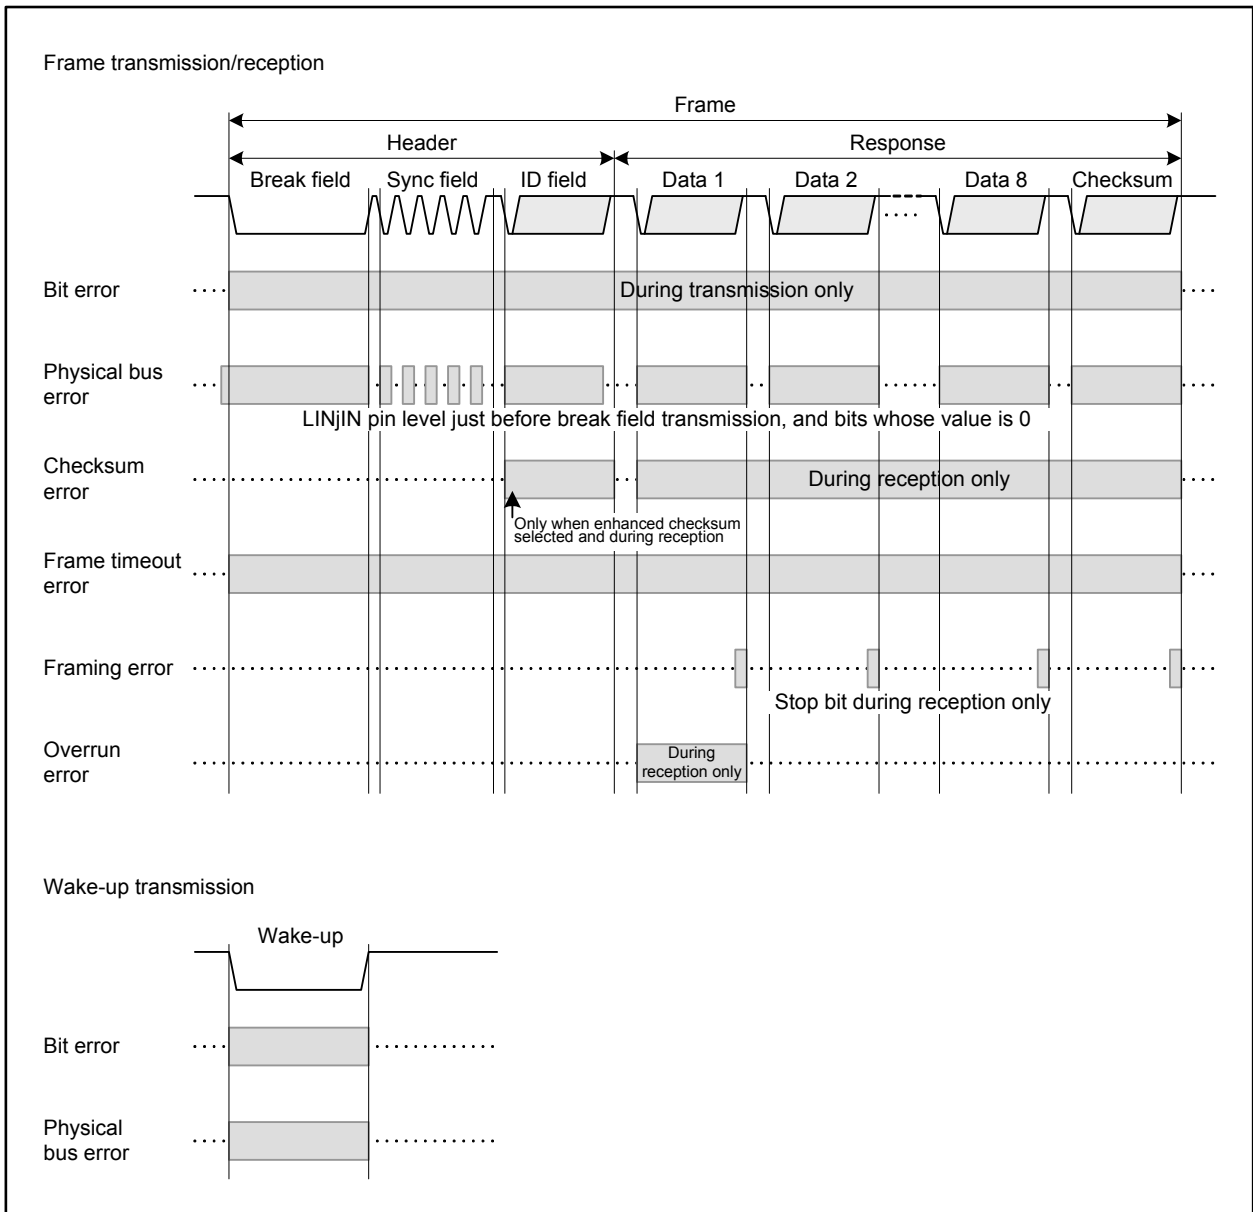

Figure 24.31 LIN Error Detection Targets (j = 0 to 3)

24.11   LIN Interrupts

The LIN module generates the LINj interrupt (j = 0 to 3) and LIN low detection interrupt.

Each channel has four interrupt sources: frame/wake-up transmit completion, frame/wake-up receive completion, error detection, and input signal low detection.

Interrupt requests by the frame/wake-up transmit completion, frame/wake-up receive completion, and error detection interrupt sources are aggregated in each channel by logical OR as an interrupt request "LINj interrupt". The input signal low detection interrupt of each channel, on the other hand, is aggregated by logical OR as a LIN low detection interrupt request.

The respective interrupt request is output when the corresponding flag in the LST register becomes 1 while the corresponding bit in the LMD0 register is 1 (interrupt enabled). No new interrupt request is generated by the other sources if any of them is 1 since multiple interrupt sources are aggregated.

Figures 24.32 and 24.33 show the block diagram of the LINj interrupt and the LIN low detection interrupt, respectively.
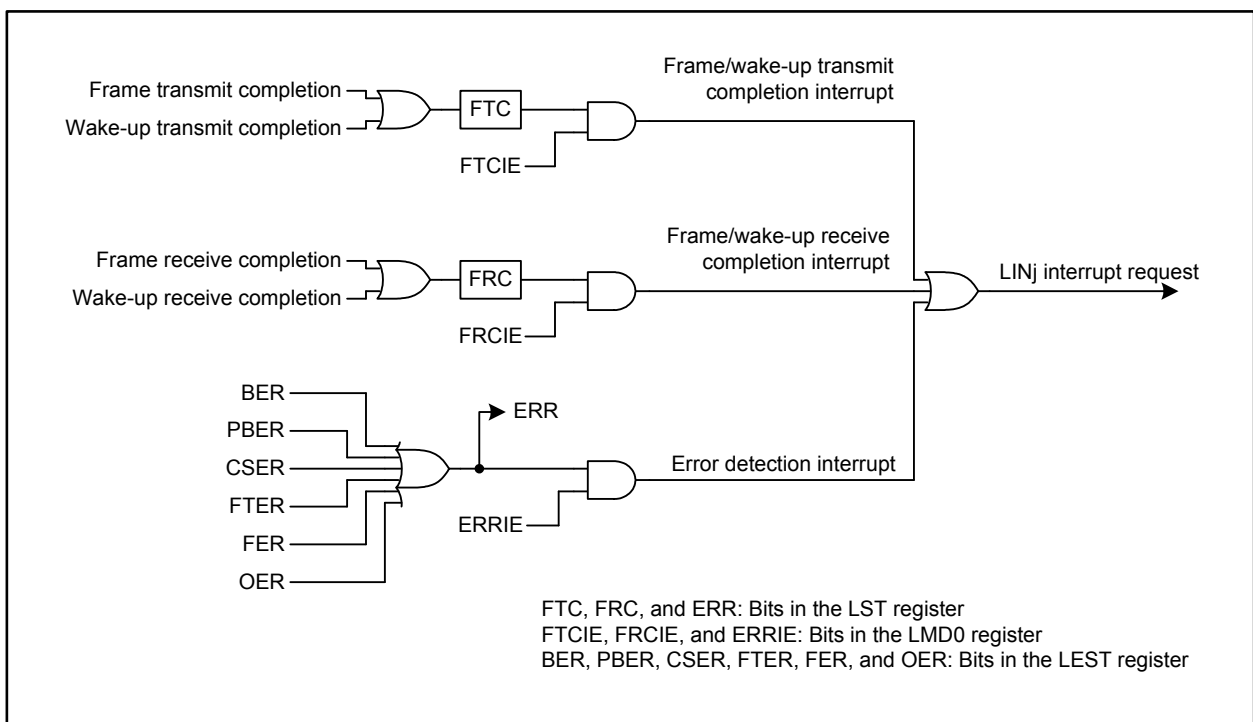

Figure 24.32 LINj Interrupt Block Diagram (j = 0 to 3)
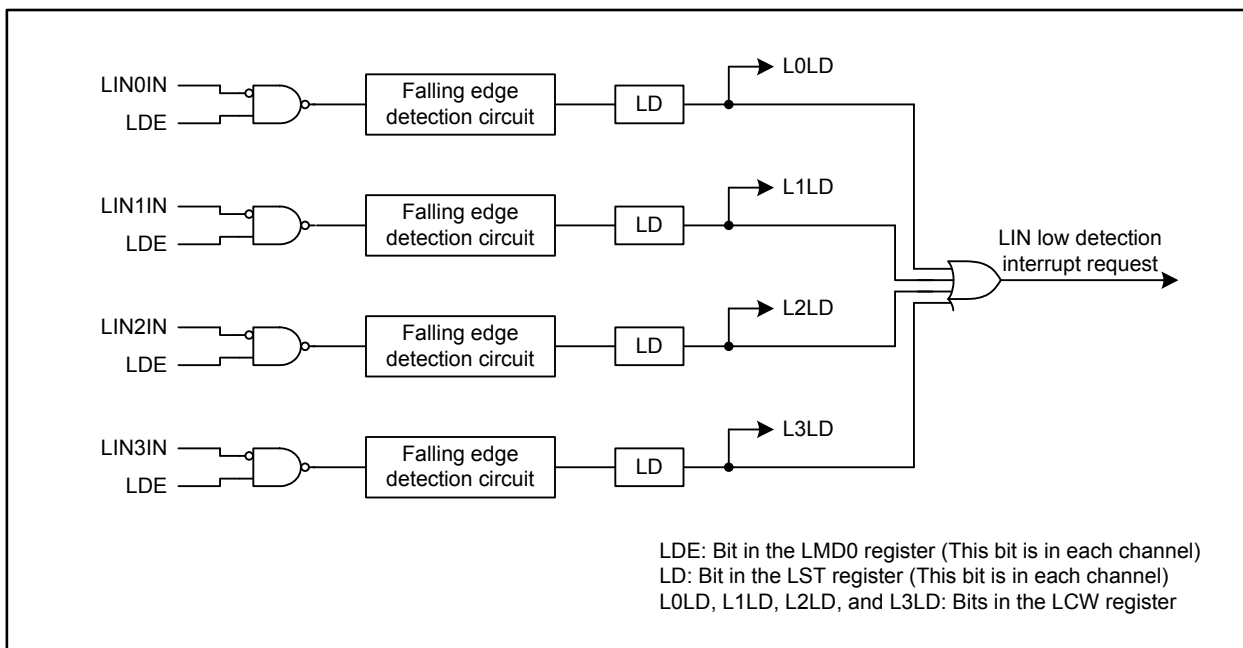

Figure 24.33 LIN Low Detection Interrupt Block Diagram

25. CAN Module

The R32C/156 Group implements two channels (CAN0 and CAN1) of the Controller Area Network (CAN) module that complies with the ISO 11898-1 standard. The CAN module transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier hereafter referred to as ID) and extended ID (29 bits).

Tables 25.1 and 25.2 list the CAN module specifications, and Figure 25.1 shows the CAN module block diagram.

Connect the CAN bus transceiver externally.

Table 25.1   CAN Module Specifications (1/2)

Item	Specification
Protocol	ISO 11898-1 compliant
Bit rate	Maximum 1 Mbps

Message boxes	32 mailboxes:
	Two selectable mailbox modes:
	• Normal mailbox mode
	  All 32 mailboxes can be indivisually configured for transmission or reception
	• FIFO mailbox mode:
	  24 mailboxes can be indivisually configured for transmission or reception.
	  4 of the remaining mailboxes can be configured for transmit FIFO and the other
	  4 mailboxes for receive FIFO

Reception	• Data frames and remote frames can be received • Selectable receiving ID format (standard ID only, extended ID only, or both IDs) • Programmable one-shot reception function • Selectable overwrite mode (message overwritten) or overrun mode (message discarded) • The reception complete interrupt can be enabled or disabled for each mailbox
Acceptance filtering	8 acceptance masks: 1 mask for every 4 mailboxes The mask can be enabled or disabled for each mailbox
Transmission	• Data frames and remote frames can be transmitted • Selectable transmitting ID format (standard ID only, extended ID only, or both IDs) • Programmable one-shot transmission function • Selectable ID priority transmit mode or mailbox number priority transmit mode • Transmission request can be aborted (A completed abort operation can be confirmed with a flag) • The transmission complete interrupt can be enabled or disabled for each mailbox
Mode transition for bus-off recovery	Mode transition for recovering from the bus-off state can be selected: • ISO 11898-1 compliant • Automatic entry to CAN halt mode at bus-off entry • Automatic entry to CAN halt mode at bus-off end • Entry to CAN halt mode by a program • Transition to the error-active state by a program

Table 25.2 CAN Module Specifications (2/2)

Item	Specification
Error status monitoring	• CAN bus errors (stuff error, form error, ACK error, CRC error, bit error, and ACK delimiter error) can be monitored • Transition to error states can be detected (error-warning, error-passive, bus-off entry, and bus-off recovery) • The error counters can be read
Time stamp function	Time stamp function using a 16-bit counter The reference clock can be selected among 1, 2, 4, and 8 bit times
Interrupt sources	6 types: • Reception complete • Transmission complete • Receive FIFO • Transmit FIFO • Error • Wake-up
CAN sleep mode	Current consumption can be reduced by stopping the CAN clock
Software support units	3 software support units: • Acceptance filter support • Mailbox search support (receive mailbox search, transmit mailbox search, and message lost search) • Channel search support
CAN clock source	Peripheral bus clock or main clock selectable
Test modes	3 test modes available for user evaluation: • Listen only mode • Self test mode 0 (external loop back) • Self test mode 1 (internal loop back)
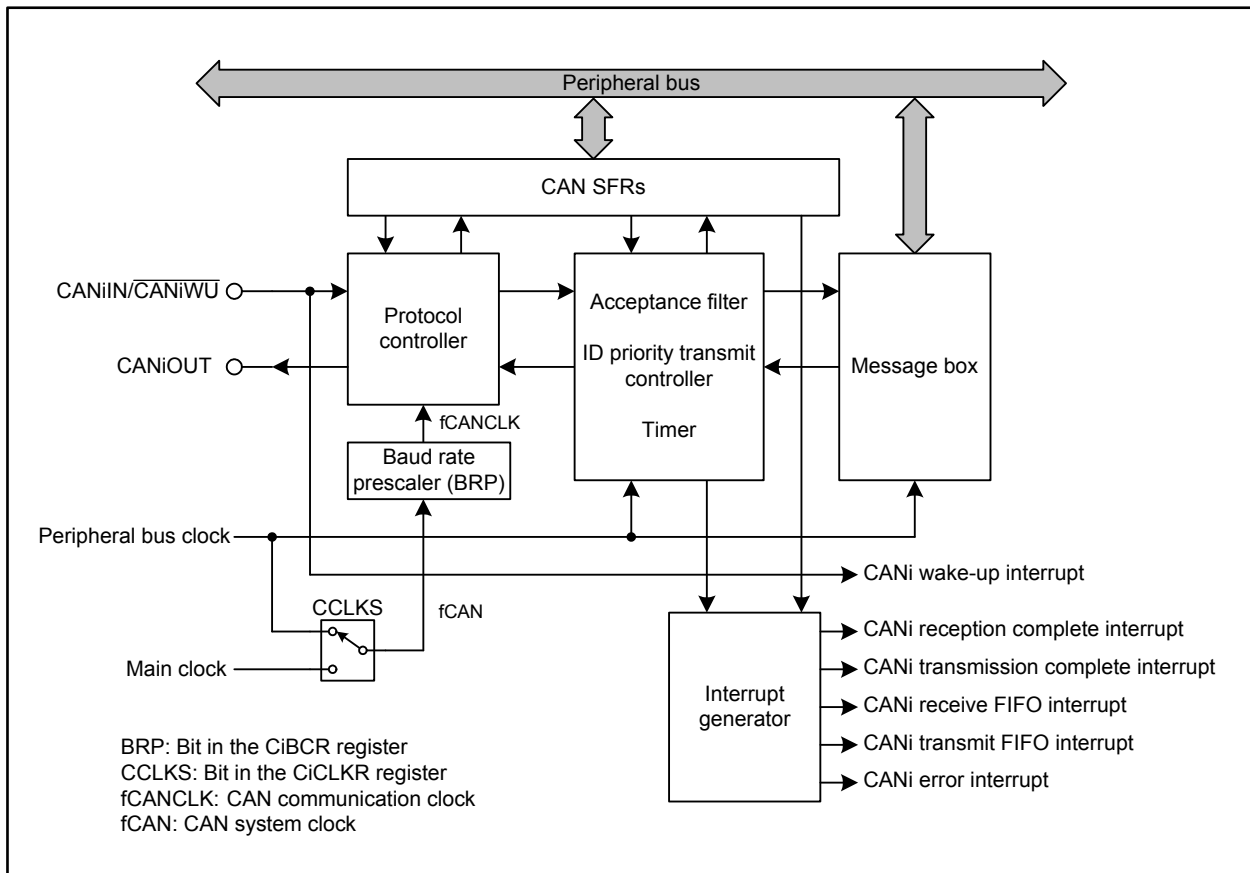

Figure 25.1   CAN Module Block Diagram (i = 0, 1)

- CANiIN/CANiOUT (i = 0, 1): CAN I/O pins
- Protocol controller: Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling, etc.
- Message box: Consists of 32 mailboxes which can be individually configured as either a transmit or receive mailbox. Each mailbox has its own ID, data length code, an 8-byte data field, and a time stamp.
- Acceptance filter: Filters received messages. Registers CiMKR0 to CiMKR7 are used for the filtering process.
- Timer: Used for the time stamp function. The timer value when storing a message into a mailbox is written as the time stamp value.
- Wake-up function: Generates a CANi wake-up interrupt request when a message is detected on the CAN bus.
- Interrupt generator: Generates the following five types of interrupts:
  - CANi reception complete interrupt
  - CANi transmission complete interrupt
  - CANi receive FIFO interrupt
  - CANi transmit FIFO interrupt
  - CANi error interrupt
- CAN SFRs: CAN-associated registers. Refer to 25.1 "CAN SFRs" for details.

25.1 CAN SFRs

CAN-associated registers are shown in Figures 25.2 to 25.11, 25.13, 25.14, 25.16 to 25.20, 25.22, and 25.24 to 25.30.

25.1.1   CANi Control Register (CiCTLR) (i = 0, 1)

CANi Control Register (i = 0, 1)

b15	b8 b7	b0	Symbol	Address	Reset Value
	0 0		C0CTLR	47F41h-47F40h	0000 0000 0000 0101b
			C1CTLR	47B41h-47B40h	0000 0000 0000 0101b

Bit Symbol	Bit Name	Function	RW
CANM	CAN Operating Mode Select Bit [1]	b1 b0 0 0 : CAN operation mode 0 1 : CAN reset mode 1 0 : CAN halt mode 1 1 : Do not use this combination	RW
SLPM	CAN Sleep Mode Bit [1, 2]	0: Mode other than CAN sleep mode 1: CAN sleep mode	RW

BOM	Bus-off Recovery Mode Select Bit [3]	b4 b3
		0 0 : Normal mode
		    (ISO 11898-1 compliant)
		0 1 : Entry to CAN halt mode
		    automatically at bus-off entry
		1 0 : Entry to CAN halt mode
		    automatically at bus-off end
		1 1 : Entry to CAN halt mode
		    (during bus-off recovery period)
		    by a program request
			RW

RBOC	Forced Recovery From Bus-off Bit [4]	0: Nothing occurred 1: Forced recovery from bus-off [5]	RW
— (b7-b6)	Reserved	Should be written with 0	RW
MBM	CAN Mailbox Mode Select Bit [3]	0: Normal mailbox mode 1: FIFO mailbox mode	RW
IDFM	ID Format Mode Select Bit [3]	b10 b9 0 0 : Standard ID mode 0 1 : Extended ID mode 1 0 : Mixed ID mode 1 1 : Do not use this combination	RW
MLM	Message Lost Mode Select Bit [3]	0: Overwrite mode 1: Overrun mode	RW
TPM	Transmit Priority Mode Select Bit [3]	0: ID priority transmit mode 1: Mailbox number priority transmit mode	RW
TSRC	Time Stamp Counter Reset Bit [6]	0: Not reset 1: Reset [5]	RW
TSPS	Time Stamp Prescaler Select Bit [3]	b15 b14 0 0 : Every bit time 0 1 : Every 2-bit time 1 0 : Every 4-bit time 1 1 : Every 8-bit time	RW

Notes:
1. When bits CANM and SLPM are changed, read the CiSTR register to ensure that the mode has been switched. Do not change bits CANM and SLPM until the mode has been switched.
2. Write to the SLPM bit in CAN reset mode or CAN halt mode. When rewriting the SLPM bit, set only this bit to 0 or 1.
3. Write to bits BOM, MBM, IDFM, MLM, TPM, and TSPS in CAN reset mode.
4. Set the RBOC bit to 1 in bus-off state.
5. Bits RBOC and TSRC are automatically set back to 0 after being set to 1. They are read as 0.
6. Set the TSRC bit to 1 in CAN operation mode.

Figure 25.2   Registers C0CTLR and C1CTLR

25.1.1.1   CANM Bit

Set the CANM bit to select one of the following modes for the CAN module: CAN operation mode, CAN reset mode, or CAN halt mode. Refer to 25.2 "Operating Modes" for details.
Set the SLPM bit to 1 to select CAN sleep mode.
Do not set the CANM bit to 11b.
When the CAN module enters CAN halt mode according to the setting of the BOM bit, the CANM bit automatically becomes 10b.

25.1.1.2   SLPM Bit

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode.
When this bit is set to 0, the CAN module exits CAN sleep mode.
Refer to 25.2 "Operating Modes" for details.

25.1.1.3   BOM Bit

Set the BOM bit to select bus-off recovery mode.

When the BOM bit is 00b, the recovery from bus-off is ISO 11898-1 compliant, i.e. the CAN module reenters CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off.

When the BOM bit is 01b, as soon as the CAN module enters the bus-off state, the CANM bit in the CiCTLR register becomes 10b (CAN halt mode) and the CAN module enters CAN halt mode (i = 0, 1). No bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR become 00h.

When the BOM bit is 10b, the CANM bit becomes 10b as soon as the CAN module enters the bus-off state. The CAN module enters CAN halt mode after recovering from the bus-off state, i.e. after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR become 00h.

When the BOM bit is 11b, the CAN module enters CAN halt mode by setting the CANM bit to 10b while the CAN module is still in the bus-off state. No bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR become 00h. However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM bit is set to 10b, a bus-off recovery interrupt request is generated.

If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM bit is 01b, or at bus-off end when the BOM bit is 10b), then the CPU request to enter CAN reset mode has higher priority.

25.1.1.4   RBOC Bit

When the RBOC bit is set to 1 (forced recovery from bus-off) in the bus-off state, the CAN module forcibly recovers from the bus-off state. This bit automatically becomes 0. The error state changes from bus-off to error-active.

When the RBOC bit is set to 1, registers CiRECR and CiTECR become 00h and the BOST bit in the CiSTR register becomes 0 (CAN module is not in bus-off state). The other registers do not change. No bus-off recovery interrupt request is generated by recovering from the bus-off state.
Use the RBOC bit only when the BOM bit is 00b (normal mode).

25.1.1.5   MBM Bit

When the MBM bit is 0 (normal mailbox mode), mailboxes [0] to [31] are configured as transmit or receive mailboxes.

When this bit is 1 (FIFO mailbox mode), mailboxes [0] to [23] are configured as transmit or receive mailboxes, mailboxes [24] to [27] are configured as transmit FIFO, and mailboxes [28] to [31] are as receive FIFO.

Transmit data is written into mailbox [24] (mailbox [24] is a window mailbox for the transmit FIFO).

Receive data is read from mailbox [28] (mailbox [28] is a window mailbox for the receive FIFO).

Table 25.3 lists the mailbox configuration.

Table 25.3   Mailbox Configuration

Mailbox	MBM Bit is 0 (Normal mailbox mode)	MBM Bit is 1 [1] (FIFO mailbox mode)
Mailboxes [0] to [23]	Normal mailbox	Normal mailbox
Mailboxes [24] to [27]		Transmit FIFO
Mailboxes [28] to [31]		Receive FIFO

Note:
1. When the MBM bit is set to 1, note the following:
    • Transmit FIFO is controlled by the CiTFCR register (i = 0, 1).
      The CiMCTLj register for mailboxes [24] to [27] is disabled (j = 0 to 31).
      Registers CiMCTL24 to CiMCTL27 cannot be used.
    • Receive FIFO is controlled by the CiRFCR register.
      The CiMCTLj register for mailboxes [28] to [31] is disabled.
      Registers CiMCTL28 to CiMCTL31 cannot be used.
    • Refer to the CiMIER register for the FIFO interrupts.
    • The corresponding bits in the CiMKIVLR register for mailboxes [24] to [31] are disabled. Set 0 to these bits.
    • Transmit/receive FIFOs can be used for both data frames and remote frames.

25.1.1.6   IDFM Bit

Set the IDFM bit to specify the ID format.

When this bit is 00b, all mailboxes (including FIFO mailboxes) handle standard IDs only.

When this bit is 01b, all mailboxes (including FIFO mailboxes) handle extended IDs only.

When this bit is 10b, all mailboxes (including FIFO mailboxes) handle both standard IDs and extended IDs. Standard IDs or extended IDs are specified by setting the IDE bit in the corresponding mailbox in normal mailbox mode. In FIFO mailbox mode, the IDE bit in the corresponding mailbox is used for mailboxes [0] to [23], the IDE bit in registers CiFIDCR0 and CiFIDCR1 is used for the receive FIFO, and the IDE bit in mailbox [24] is used for the transmit FIFO.

Do not set 11b to the IDFM bit.

25.1.1.7   MLM Bit

Set the MLM bit to specify the operation when a new message is captured in an unread mailbox. Overwrite mode or overrun mode can be selected. All mailboxes (including the receive FIFO) are set to either overwrite mode or overrun mode.

When the MLM bit is 0, all mailboxes are set to overwrite mode and the new message overwrites the old message.
When this bit is 1, all mailboxes are set to overrun mode and the new message is discarded.

25.1.1.8   TPM Bit

Set the TPM bit to specify the priority of modes when transmitting messages.
ID priority transmit mode or mailbox number priority transmit mode can be selected.
All mailboxes are set to either ID priority transmission or mailbox number priority transmission.

When the TPM bit is 0, ID priority transmit mode is selected and transmission priority complies with the CAN bus arbitration rule, as specified in the ISO 11898-1 standard. In ID priority transmit mode, mailboxes [0] to [31] (in normal mailbox mode), mailboxes [0] to [23] (in FIFO mailbox mode), and the transmit FIFO are compared with the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.

Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a transmit FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.

When the TPM bit is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (mailboxes [0] to [23]).

25.1.1.9   TSRC Bit

Set the TSRC bit to reset the time stamp counter.
When this bit is set to 1, the CiTSR register becomes 0000h (i = 0, 1). It automatically becomes 0.

25.1.1.10 TSPS Bit

Set the TSPS bit to select the prescaler for the time stamp.
The reference clock for the time stamp can be selected among 1, 2, 4, and 8 bit times.

25.1.2 CANi Clock Select Register (CiCLKR) (i = 0, 1)

CANi Clock Select Register (i = 0, 1)

b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value
0 ⊠ ⊠ 0 0 ⊠ 0	C0CLKR	47F47h	000X 0000b
	C1CLKR	47B47h	000X 0000b

Bit Symbol	Bit Name	Function	RW
CCLKS	CAN Clock Source Select Bit [1]	0: Peripheral bus clock 1: Main clock [2]	RW
— (b1)	Reserved	Should be written with 0	RW
— (b2)	No register bit; should be written with 0 and read as 0		—
— (b3)	Reserved	Should be written with 0	RW
— (b4)	Reserved	Should be written with 0 and read as undefined value	RW
— (b6-b5)	No register bits; should be written with 0 and read as 0		—
— (b7)	Reserved	Should be written with 0	RW

Notes:
1. Write to the CCLKS bit in CAN reset mode.
2. To set the CCLKS bit to 1, the frequency of the peripheral bus clock should be equal to or higher than the frequency of the main clock.

Figure 25.3 Registers C0CLKR and C1CLKR

25.1.2.1 CCLKS Bit

When the CCLKS bit is set to 0, the peripheral bus clock generated with the PLL frequency synthesizer is used for the CAN clock source (fCAN).

When this bit is set to 1, the main clock input from the external XIN pin is used for fCAN instead of the PLL frequency synthesizer.

25.1.3   CANi Bit Configuration Register (CiBCR) (i = 0, 1)

CANi Bit Configuration Register (i = 0, 1) [1, 2]

Symbol	Address	Reset Value
C0BCR	47F46h-47F44h	00 0000h
C1BCR	47B46h-47B44h	00 0000h

Bit Symbol	Bit Name	Function	RW

— (b23-b22)	No register bits; should be written with 0 and read as 0		—

Notes:
1. Set the CiBCR register before entering CAN halt mode from CAN reset mode or CAN operation mode from CAN reset mode. Once this register is set, it can be rewritten in CAN reset mode or CAN halt mode.
2. The CiBCR register consists of 24 bits. A 32-bit read/write access should be performed carefully as to not rewrite the CiCLKR register.

Figure 25.4   Registers C0BCR and C1BCR

Refer to 25.3 "CAN Communication Speed Configuration" for the bit timing configuration.

25.1.3.1 BRP Bit

The BRP bit sets the frequency of the CAN communication clock (fCANCLK).
One fCANCLK cycle is measured as Time Quantum (Tq).

25.1.3.2 TSEG1 Bit

Set the TSEG1 bit to specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with the value of Tq.
A value from 4 to 16 Tq can be set.

25.1.3.3 TSEG2 Bit

Set the TSEG2 bit to specify the length of phase buffer segment TSEG2 (PHASE_SEG2) with the value of Tq.
A value from 2 to 8 Tq can be set.
Set the value smaller than that of the TSEG1 bit.

25.1.3.4 SJW Bit

Set the SJW bit to specify the resynchronization jump width with the value of Tq.
A value from 1 to 4 Tq can be set.
Set the value smaller than or equal to that of the TSEG2 bit.

25.1.4   CANi Mask Register k (CiMKRk) (i = 0, 1; k = 0 to 7)

CANi Mask Register k (i = 0, 1; k = 0 to 7) [1]

SID	Standard ID Bit	0: Corresponding SID bit is not compared 1: Corresponding SID bit is compared	RW
— (b31-b29)	Reserved	Should be written with 0	RW

Note:
1. Write to registers CiMKR0 to CiMKR7 in CAN reset mode or CAN halt mode.

Figure 25.5   Registers C0MKR0 to C1MKR7

Refer to 25.5 "Acceptance Filtering and Masking Function" for the masking function in FIFO mailbox mode.

25.1.4.1   EID Bit

The EID bit is the filter mask bit corresponding to the CAN extended ID bit. This bit is used to receive extended ID messages.
When the EID bit is 0, the corresponding EID bit in a received message is not compared.
When this bit is 1, the corresponding EID bit in a received message is compared.

25.1.4.2   SID Bit

The SID bit is the filter mask bit corresponding to the CAN standard ID bit. This bit is used to receive both standard ID and extended ID messages.
When the SID bit is 0, the corresponding SID bit in a received message is not compared.
When this bit is 1, the corresponding SID bit in a received message is compared.

25.1.5   CANi FIFO Received ID Compare Register n (CiFIDCR0 and CiFIDCR1) (i = 0, 1; n = 0, 1)

CANi FIFO Received ID Compare Register n (i = 0, 1; n = 0, 1) [1]

	Symbol	Address	Reset Value
b31 b28 b18 b17 b0	C0FIDCR0	47E23h-47E20h	Undefined
	C0FIDCR1	47E27h-47E24h	Undefined
	C1FIDCR0	47A23h-47A20h	Undefined
	C1FIDCR1	47A27h-47A24h	Undefined

Bit Symbol	Bit Name	Function	RW
EID	Extended ID Bit	0: Corresponding EID bit is 0 1: Corresponding EID bit is 1	RW
SID	Standard ID Bit	0: Corresponding SID bit is 0 1: Corresponding SID bit is 1	RW
— (b29)	Reserved	Should be written with 0	RW
RTR	Remote Frame Request Bit	0: Data frame 1: Remote frame	RW
IDE	ID Extension Bit [2]	0: Standard ID 1: Extended ID	RW

Notes:
1. Write to registers CiFIDCR0 and CiFIDCR1 in CAN reset mode or CAN halt mode.
2. The IDE bit is enabled when the IDFM bit in the CiCTLR register is 10b (mixed ID mode). When the IDFM bit is either 00b (standard ID mode) or 01b (extended ID mode), the IDE bit should be written with 0.

Figure 25.6   Registers C0FIDCR0 to C1FIDCR1

Registers CiFIDCR0 and CiFIDCR1 are enabled when the MBM bit in the CiCTLR register is set to 1 (FIFO mailbox mode). Bits EID, SID, RTR, and IDE in registers CiMB28 to CiMB31 are disabled. Refer to 25.5 "Acceptance Filtering and Masking Function" for details on using these registers.

25.1.5.1   EID Bit

The EID bit sets the extended ID of data frames and remote frames. This bit is used to receive extended ID messages.

25.1.5.2   SID Bit

The SID bit sets the standard ID of data frames and remote frames. This bit is used to receive both standard ID and extended ID messages.

25.1.5.3   RTR Bit

The RTR bit sets the specified frame format of data frames or remote frames.
This bit specifies the following operations:
- When both RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to 0, only data frames can be received (i = 0, 1).
- When both RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to 1, only remote frames can be received.
- When the RTR bits in registers CiFIDCR0 and CiFIDCR1 are set with different values, both data frames and remote frames can be received.

25.1.5.4   IDE Bit

The IDE bit sets the ID format of standard ID or extended ID.
This bit is enabled when the IDFM bit in the CiCTLR register is 10b (mixed ID mode).
When the IDFM bit is 10b, the IDE bit specifies the following operations:
- When both IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to 0, only standard ID frames can be received.
- When both IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to 1, only extended ID frames can be received.
- When the IDE bits in registers CiFIDCR0 and CiFIDCR1 are set with different values, both standard ID and extended ID frames can be received.

25.1.6   CANi Mask Invalid Register (CiMKIVLR) (i = 0, 1)

CANi Mask Invalid Register (i = 0, 1) (1)

FIFO mailbox mode

b31 b24 b23   b0

Bit Symbol	Bit Name	Function	RW
— (b23-b0)	Mask Invalid Bit	0: Mask valid 1: Mask invalid	RW
— (b31-b24)	Reserved	Should be written with 0	RW

Note:
1. Write to the CiMKIVLR register in CAN reset mode or CAN halt mode.

Figure 25.7   Registers C0MKIVLR and C1MKIVLR

Each bit corresponds to the mailbox with the same number. When each bit is 1, the acceptance mask for the mailbox corresponding to the bit number is disabled. In this case, a received message is stored in the mailbox only if its ID matches bits SID and EID in the CiMBj register (j = 0 to 31).

25.1.7   CANi Mailbox (CiMBj) (i = 0, 1; j = 0 to 31)

Table 25.4 lists the CANi mailbox memory mapping, and Table 25.5 lists the CAN data frame structure. The reset value of the CANi mailbox is undefined.

Table 25.4   CANi Mailbox Memory Mapping (i = 0, 1)

TSH	Time Stamp Upper Byte	00h to FFh	RW

Notes:
1. Write to the CiMBj register only when the associated CiMCTLj register is 00h and the corresponding mailbox is not processing an abort request.
2. Refer to the memory mapping table for CANi mailbox on the previous page for detailed addresses.
3. If the mailbox has received a standard ID message, the EID bit in the mailbox is undefined.
4. The IDE bit is enabled when the IDFM bit in the CiCTLR register is 10b (mixed ID mode).
   When the IDFM bit is either 00b (standard ID mod) or 01b (extended ID mode), it should be written with 0.
5. If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.
6. If the mailbox has received a remote frame, the previous values of DATA0 to DATA7 in the mailbox are retained.

Figure 25.8   Registers C0MBj and C1MBj

The previous value of each mailbox is retained unless a new message is received.

25.1.7.1   EID Bit

The EID bit sets the extended ID of data frames and remote frames. This bit is used to transmit or receive extended ID messages.

25.1.7.2   SID Bit

The SID bit sets the standard ID of data frames and remote frames. This bit is used to transmit or receive both standard ID and extended ID messages.

25.1.7.3   RTR Bit

The RTR bit sets the frame format of data frames or remote frames.
This bit specifies the following operations:
- The receive mailbox receives only frames with the format specified by the RTR bit.
- The transmit mailbox transmits according to the frame format specified by the RTR bit.
- The receive FIFO mailbox receives the data frame, remote frame, or both frames specified by the RTR bit in registers CiFIDCR0 and CiFIDCR1 (i = 0, 1).
- The transmit FIFO mailbox transmits the data frame or remote frame specified by the RTR bit in the relevant transmitting message.

25.1.7.4   IDE Bit

The IDE bit sets the ID format of standard IDs or extended IDs.
This bit is enabled when the IDFM bit in the CiCTLR register is 10b (mixed ID mode).
When the IDFM bit is 10b, the IDE bit specifies the following operations:
- The receive mailbox receives only the ID format specified by the IDE bit.
- The transmit mailbox transmits according to the ID format specified by the IDE bit.
- The receive FIFO mailbox receives messages with the standard ID, extended ID, or both IDs specified by the IDE bit in registers CiFIDCR0 and CiFIDCR1.
- The transmit FIFO mailbox transmits messages with the standard ID or extended ID specified by the IDE bit in the relevant transmitting message.

25.1.7.5   DLC

The DLC sets the number of data bytes to be transmitted in a data frame. When data is requested using a remote frame, the number of data bytes to be requested is set.

When a data frame is received, the number of received data bytes is stored. When a remote frame is received, the number of requested data bytes is stored.

Table 25.6 lists the data length corresponding to the DLC.

Table 25.6   Data Length Corresponding to the DLC

DLC[3]	DLC[2]	DLC[1]	DLC[0]	Data Length
0	0	0	0	0 bytes
0	0	0	1	1 byte
0	0	1	0	2 bytes
0	0	1	1	3 bytes
0	1	0	0	4 bytes
0	1	0	1	5 bytes
0	1	1	0	6 bytes
0	1	1	1	7 bytes
1	X	X	X	8 bytes

X: Any value

25.1.7.6   DATA0 to DATA7

DATA0 to DATA7 store the transmitted or received CAN message data. Transmission or reception starts from DATA0. The bit order on the CAN bus is MSB first, and transmission or reception starts from bit 7.

25.1.7.7   TSL and TSH

TSL and TSH store the counter value of the time stamp when received messages are stored in the mailbox.

25.1.8   CANi Mailbox Interrupt Enable Register (CiMIER) (i = 0, 1)

CANi Mailbox Interrupt Enable Register (i = 0, 1) [1, 2]

Normal mailbox mode

b31   b0

Symbol	Address	Reset Value
C0MIER	47E2Fh-47E2Ch	Undefined
C1MIER	47A2Fh-47A2Ch	Undefined

Bit Symbol	Bit Name	Function	RW
— (b31-b0)	Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW

FIFO mailbox mode

b31 b24b23   b0

Bit Symbol	Bit Name	Function	RW
— (b23-b0)	Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW
— (b24)	Transmit FIFO Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW
— (b25)	Transmit FIFO Interrupt Generation Timing Control Bit	Transmit FIFO interrupt request is generated 0: Every time transmission is completed 1: When transmit FIFO becomes empty due to completion of transmission	RW
— (b27-b26)	Reserved	Should be written with 0	RW
— (b28)	Receive FIFO Interrupt Enable Bit	0: Interrupt disabled 1: Interrupt enabled	RW
— (b29)	Receive FIFO Interrupt Generation Timing Control Bit	Receive FIFO interrupt request is generated 0: Every time reception is completed 1: When receive FIFO becomes buffer warning by completion of reception [3]	RW
— (b31-b30)	Reserved	Should be written with 0	RW

Notes:
1. Write to the CiMIER register only when the associated CiMCTLj register is 00h and the corresponding mailbox is not processing a transmission or reception abort request (j = 0 to 31).
2. In FIFO mailbox mode, change the bits in the CiMIER register for the associated FIFO only when:
   - The TFE bit in the CiTFCR register is 0 and the TFEST bit is 1, and
   - The RFE bit in the CiRFCR register is 0 and the RFEST bit is 1.
3. No interrupt request is generated when the receive FIFO becomes buffer warning from full.

Figure 25.9   Registers C0MIER and C1MIER

Interrupts can be individually enabled for each mailbox.
In normal mailbox mode (bits 0 to 31) and in FIFO mailbox mode (bits 0 to 23), each bit corresponds to the mailbox with the same number. These bits enable or disable transmission/reception complete interrupts for the corresponding mailboxes.
In FIFO mailbox mode, bits 24, 25, 28, and 29 specify whether transmit/receive FIFO interrupts are enabled/disabled and timing when interrupt requests are generated.
"Buffer warning" indicates a state in which the third unread message is stored in the receive FIFO.

25.1.9   CANi Message Control Register j (CiMCTLj) (i = 0, 1; j = 0 to 31)

CANi Message Control Register j (i = 0, 1; j = 0 to 31) [1, 2]

C1MCTL0 to C1MCTL31	47B20h to 47B3Fh	00h

Bit Symbol	Bit Name	Function	RW
When the TRMREQ bit is 0 and the RECREQ bit is 1			
NEWDATA	Reception Complete Flag [3, 4]	0: No data has been received or 0 is written to the NEWDATA bit 1: A new message is being stored or has been stored to the mailbox	RW
INVALDATA	Reception-in-progress Status Flag	0: Message valid 1: Message being updated	RO
MSGLOST	Message Lost Flag [3, 4]	0: Message is not overwritten or overrun 1: Message is overwritten or overrun	RW
When the TRMREQ bit is 1 and the RECREQ bit is 0			
SENTDATA	Transmission Complete Flag [3, 4]	0: Transmission is not completed (pending) 1: Transmission is completed (successful)	RW
TRMACTIVE	Transmission-in-progress Status Flag	0: Transmission is pending or transmission is not requested 1: From acceptance of transmission request to completion of transmission, or error/arbitration lost	RO
TRMABT	Transmission Abort Complete Flag [3, 4]	0: Transmission has started, transmission abort failed because transmission is completed, or transmission abort is not requested 1: Transmission abort is completed	RW
— (b3)	No register bit; should be written with 0 and read as 0		—
ONESHOT	One-shot Enable Bit [5]	0: One-shot reception or one-shot transmission disabled 1: One-shot reception or one-shot transmission enabled	RW
— (b5)	No register bit; should be written with 0 and read as 0		—
RECREQ	Receive Mailbox Set Bit [4, 6, 7]	0: Not configured for reception 1: Configured for reception	RW
TRMREQ	Transmit Mailbox Set Bit [4, 6]	0: Not configured for transmission 1: Configured for transmission	RW

Notes:
1. Write to the CiMCTLj register in CAN operation mode or CAN halt mode.
2. Do not use registers CiMCTL24 to CiMCTL31 in FIFO mailbox mode.
3. It can only be set to 0. Writing 1 to this bit has no effect.
4. When writing 0 to bits NEWDATA, SENTDATA, MSGLOST, TRMABT, RECREQ, and TRMREQ by a program, use the MOV instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.
5. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1. To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming it has been set to 0.
   To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1. To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message has been transmitted or aborted.
6. Do not set both the RECREQ and TRMREQ bits to 1.
7. When setting the RECREQ bit to 0, set bits MSGLOST, NEWDATA, RECREQ to 0 simultaneously.

Figure 25.10 Registers C0MCTLj and C1MCTLj

25.1.9.1   NEWDATA Bit

The NEWDATA bit becomes 1 when a new message is being stored or has been stored to the mailbox.
The timing for setting this bit to 1 is simultaneous with the INVALDATA bit.
The NEWDATA bit is set to 0 by writing 0 by a program.
It cannot be set to 0 by a program while the related INVALDATA bit is 1.

25.1.9.2   SENTDATA Bit

The SENTDATA bit becomes 1 when data transmission from the corresponding mailbox is completed.
This bit is set to 0 by writing 0 by a program.
Set the TRMREQ bit to 0 before setting the SENTDATA bit to 0.
Bits SENTDATA and TRMREQ cannot be set to 0 simultaneously.
To transmit a new message from the corresponding mailbox, set the SENTDATA bit to 0.

25.1.9.3   INVALDATA Bit

After a message has been received, the INVALDATA bit becomes 1 while the received message is
being updated into the corresponding mailbox.
This bit becomes 0 immediately after the message has been stored. When the mailbox is read while
this bit is 1, the data is undefined.

25.1.9.4   TRMACTIVE Bit

The TRMACTIVE bit becomes 1 when the corresponding mailbox of the CAN module begins
transmitting a message.
This bit becomes 0 when the CAN module loses CAN bus arbitration, a CAN bus error occurs, or data
transmission is completed.

25.1.9.5   MSGLOST Bit

While the NEWDATA bit is 1, the MSGLOST bit becomes 1 when the mailbox is overwritten or overrun
by a newly received message. This bit becomes 1 at the end of the sixth bit of EOF.
This bit is set to 0 by writing 0 by a program.
In both overwrite and overrun modes, during five cycles of the peripheral bus clock following the sixth
bit of EOF, the MSGLOST bit does not become 0 even if it is set to 0 by a program.

25.1.9.6   TRMABT Bit

The TRMABT bit becomes 1 in the following cases:
  • Following a transmission abort request, the transmission abort is completed before starting
    transmission.
  • Following a transmission abort request, the CAN module detects CAN bus arbitration lost or a CAN
    bus error.
  • In one-shot transmission mode (the RECREQ bit is 0, the TRMREQ bit is 1, and the ONESHOT bit
    is 1), the CAN module detects CAN bus arbitration lost or a CAN bus error.
The TRMABT bit does not become 1 when data transmission is completed. In this case, the
SENTDATA bit becomes 1.
The TRMABT bit can be set to 0 by a program.

25.1.9.7   ONESHOT Bit

The ONESHOT bit can be used in receive mode and transmit mode.

(1) One-shot Receive Mode

When the ONESHOT bit is set to 1 in receive mode (the RECREQ bit is 1 and the TRMREQ bit is 0), the mailbox receives a message only once. The mailbox does not behave as a receive mailbox after having received a message once. The behavior of bits NEWDATA and INVALDATA is the same as in normal reception mode. In one-shot receive mode, the MSGLOST bit does not become 1.
To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it has been set to 0.

(2) One-shot Transmit Mode

When the ONESHOT bit is set to 1 in transmit mode (the RECREQ bit is 0 and the TRMREQ bit is 1), the CAN module transmits a message only once. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration lost occurs. When the transmission is completed, the SENTDATA bit becomes 1. If the transmission cannot be completed due to a CAN bus error or CAN bus arbitration lost, the TRMABT bit becomes 1.
Set the ONESHOT bit to 0 after the SENTDATA or TRMABT bit is set to 1.

25.1.9.8   RECREQ Bit

Set the RECREQ bit to select one of the receive modes shown in Table 25.11.
When the RECREQ bit is set to 1, the corresponding mailbox is configured to receive a data frame or a remote frame.
When this bit is set to 0, the corresponding mailbox is not configured for reception of a data frame or a remote frame.
Due to hardware protection, the RECREQ bit cannot be set to 0 by a program during the following period:
Hardware protection is started
   • from the acceptance filter procedure (the beginning of the CRC field)
Hardware protection is released
   • for the mailbox that is specified to receive the incoming message, after the received data is stored into the mailbox or a CAN bus error occurs (i.e. a maximum period of hardware protection is from the beginning of the CRC field to the end of the seventh bit of EOF)
   • for the other mailboxes, after the acceptance filter procedure
   • if no mailbox is specified to receive the message, after the acceptance filter procedure
When setting the RECREQ bit to 1, do not set 1 to the TRMREQ bit.
To change the configuration of a mailbox from transmit to receive, first abort the transmission and then set bits SENTDATA and TRMABT to 0 before changing to receive.

25.1.9.9   TRMREQ Bit

The TRMREQ bit selects transmit modes shown in Table 25.11.
When this bit is set to 1, the corresponding mailbox is configured to transmit a data frame or a remote frame.
When this bit is set to 0, the corresponding mailbox is not configured to transmit a data frame or a remote frame.
If the TRMREQ bit is changed from 1 to 0 to cancel the corresponding transmission request, either the TRMABT or SENTDATA bit is set to 1.
When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1.
To change the configuration of a mailbox from receive to transmit, first abort the reception and then set bits NEWDATA and MSGLOST to 0 before changing to transmit.

25.1.10 CANi Receive FIFO Control Register (CiRFCR) (i = 0, 1)

CANi Receive FIFO Control Register (i = 0, 1) [1]

b7 b6 b5 b4 b3 b2 b1 b0

Symbol	Address	Reset Value
C0RFCR	47F48h	1000 0000b
C1RFCR	47B48h	1000 0000b

Bit Symbol	Bit Name	Function	RW
RFE	Receive FIFO Enable Bit [2]	0: Receive FIFO disabled 1: Receive FIFO enabled	RW
RFUST	Receive FIFO Unread Message Number Status Bit	b3 b2 b1 0 0 0 : No unread messages 0 0 1 : 1 unread message 0 1 0 : 2 unread messages 0 1 1 : 3 unread messages 1 0 0 : 4 unread messages 1 0 1 : Reserved 1 1 0 : Reserved 1 1 1 : Reserved	RO
RFMLF	Receive FIFO Message Lost Flag [3]	0: No receive FIFO message lost has occurred 1: Receive FIFO message lost has occurred	RW
RFFST	Receive FIFO Full Status Bit	0: Receive FIFO is not full 1: Receive FIFO is full (4 unread messages)	RO

RFEST	Receive FIFO Empty Status Bit	0: Unread message in receive FIFO 1: No unread message in receive FIFO	RO

Notes:
1. Write to the CiRFCR register in CAN operation mode or CAN halt mode.
2. When setting the RFE bit to 0, set the RFMLF bit to 0 as well.
3. It can only be set to 0. Writing 1 to this bit has no effect.

Figure 25.11 Registers C0RFCR and C1RFCR

25.1.10.1 RFE Bit

When the RFE bit is set to 1, the receive FIFO is enabled.
When this bit is set to 0, the receive FIFO is disabled for reception and becomes empty (the RFEST bit is 1).
Do not set this bit to 1 in normal mailbox mode (the MBM bit in the CiCTLR register is 0 (i = 0, 1)).
Due to hardware protection, the RFE bit cannot be set to 0 by a program during the following period:
Hardware protection is started
  • from the acceptance filter procedure (the beginning of the CRC field)
Hardware protection is released
  • if the receive FIFO is specified to receive the incoming message, after the received data is stored into the receive FIFO or a CAN bus error occurs (i.e. a maximum period of hardware protection is from the beginning of the CRC field to the end of the seventh bit of EOF).
  • if the receive FIFO is not specified to receive the message, after the acceptance filter procedure.

25.1.10.2 RFUST Bit

The RFUST bit indicates the number of unread messages in the receive FIFO.
The value of this bit is initialized to 000b when the RFE bit is set to 0.

25.1.10.3 RFMLF Bit

The RFMLF bit becomes 1 (receive FIFO message lost has occurred) when the receive FIFO receives a new message and the receive FIFO is full. This bit becomes 1 at the end of the sixth bit of EOF.
The RFMLF bit is set to 0 by writing 0 by a program.
In both overwrite and overrun modes, this bit cannot be set to 0 (no receive FIFO message lost has occurred) by a program due to hardware protection during the five cycles of the peripheral bus clock following the sixth bit of EOF, when the receive FIFO is full and determined to receive the message.

25.1.10.4 RFFST Bit

The RFFST bit becomes 1 (receive FIFO is full) when there are four unread messages in the receive FIFO. This bit becomes 0 (receive FIFO is not full) when there are less than four unread messages in the receive FIFO. This bit becomes 0 when the RFE bit is 0.

25.1.10.5 RFWST Bit

The RFWST bit becomes 1 (receive FIFO is buffer warning) when there are three unread messages in the receive FIFO. This bit becomes 0 (receive FIFO is not buffer warning) when there are less than three or equal to four unread messages in the receive FIFO. This bit becomes 0 when the RFE bit is 0.

25.1.10.6 RFEST Bit

The RFEST bit becomes 1 (no unread message in receive FIFO) when there are no unread messages in the receive FIFO. This bit becomes 1 when the RFE bit is set to 0. The RFEST bit becomes 0 (unread message in receive FIFO) when there is one or more unread messages in the receive FIFO.

Figure 25.12 shows receive FIFO mailbox operation.
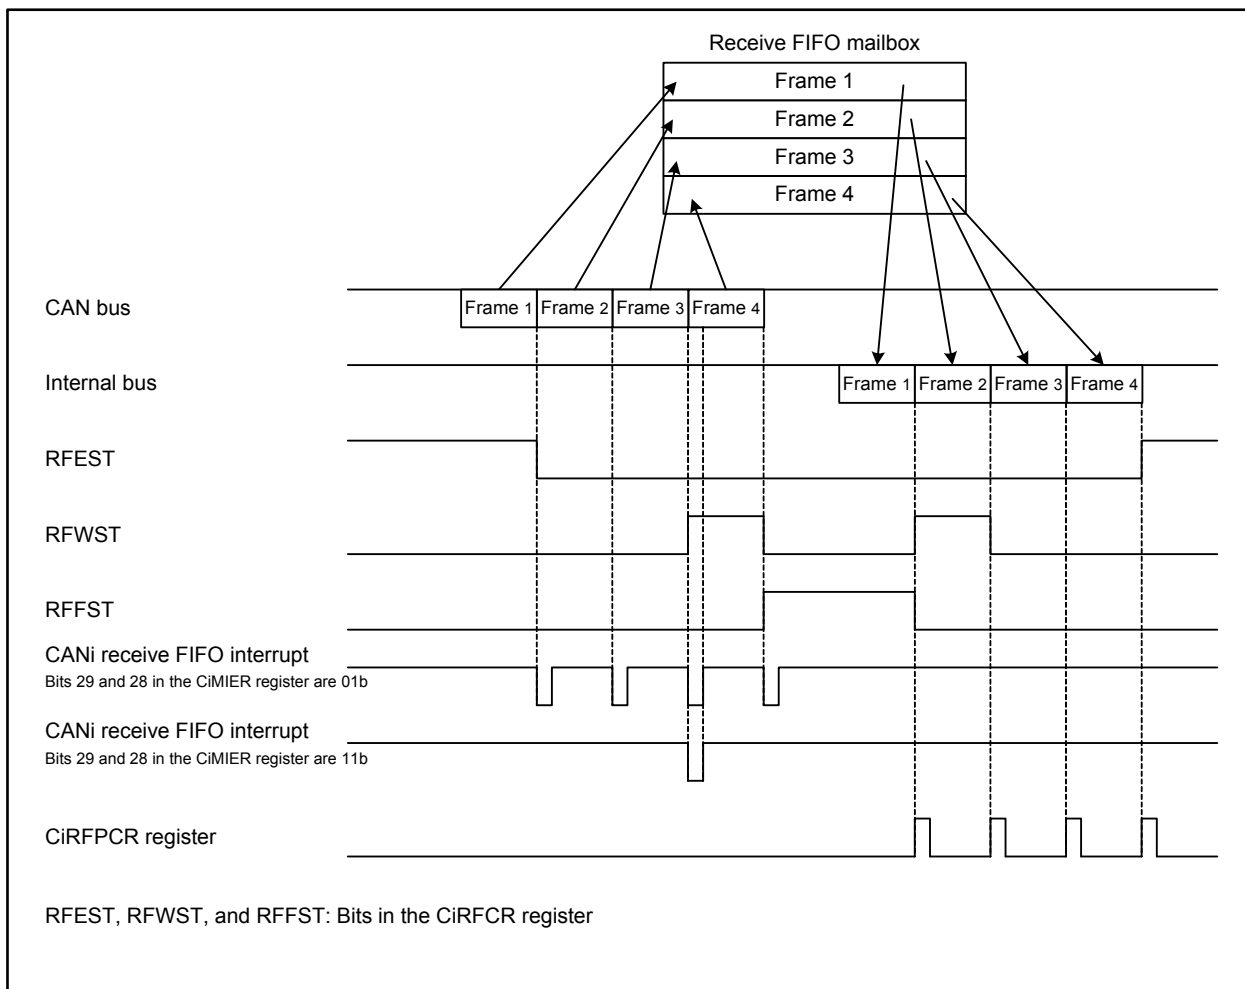

Figure 25.12   Receive FIFO Mailbox Operation (Bits 29 and 28 in CiMIER Register are 01b and 11b) (i = 0, 1)

	C1RFPCR 47B49h Undefined

Function	Setting Value	RW
The CPU-side pointer for the receive FIFO increments by writing FFh	FFh	WO
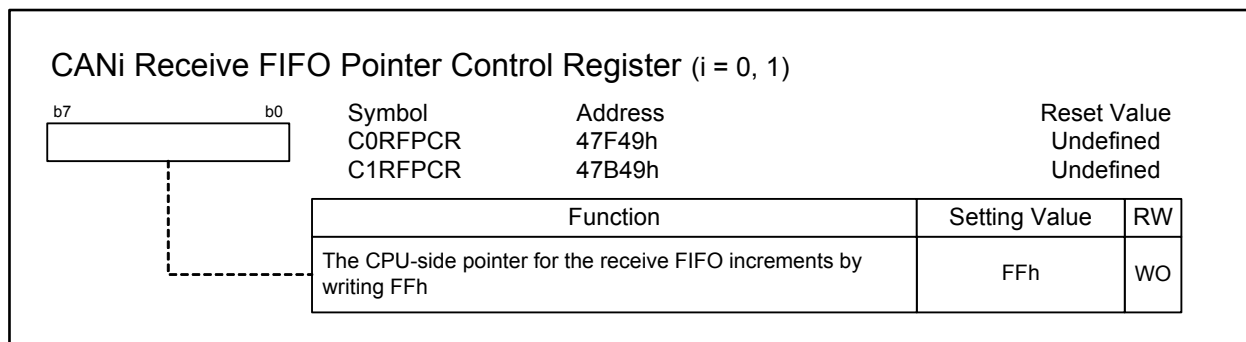

Figure 25.13 Registers C0RFPCR and C1RFPCR

When there are messages in the receive FIFO, write FFh to the CiRFPCR register by a program to increment the CPU-side pointer for the receive FIFO to the next mailbox location.

Do not write to the CiRFPCR register when the RFE bit in the CiRFCR register is 0 (receive FIFO disabled).

Both the CAN-side pointer and the CPU-side pointer increment when a new message is received and the RFFST bit is 1 (receive FIFO is full) in overwrite mode. When the RFMLF bit is 1 in this condition, the CPU-side pointer does not increment by writing to the CiRFPCR register by a program.

25.1.12   CANi Transmit FIFO Control Register (CiTFCR) (i = 0, 1)

CANi Transmit FIFO Control Register (i = 0, 1) [1]

Note:
1. Write to the CiTFCR register in CAN operation mode or CAN halt mode.

Figure 25.14   Registers C0TFCR and C1TFCR

25.1.12.1   TFE Bit

When the TFE bit is set to 1, the transmit FIFO is enabled.
When this bit is set to 0, the transmit FIFO becomes empty (TFEST bit is 1) and then unsent messages from the transmit FIFO are lost as described below:
- If a message from the transmit FIFO is not scheduled for the next transmission or during transmission.
- Following the completion of a transmission, a CAN bus error, CAN bus arbitration lost, or entry to CAN halt mode if a message from the transmit FIFO is scheduled for the next transmission or already during transmission.

Before setting the TFE bit to 1 again, ensure that the TFEST bit is 1.
After setting the TFE bit to 1, write transmit data to the CiMB24 register.
Do not set this bit to 1 in normal mailbox mode (MBM bit in the CiCTLR register is 0).

25.1.12.2   TFUST Bit

The TFUST bit indicates the number of unsent messages in the transmit FIFO.
After the TFE bit is set to 0, the value of the TFUST bit is initialized to 000b when transmission abort or transmission is completed.

25.1.12.3 TFFST Bit

The TFFST bit becomes 1 (transmit FIFO is full) when there are four unsent messages in the transmit FIFO. This bit becomes 0 (transmit FIFO is not full) when there are less than four unsent messages in the transmit FIFO. This bit becomes 0 when a transmission from the transmit FIFO has been aborted.

25.1.12.4 TFEST Bit

The TFEST bit becomes 1 (no unsent message in transmit FIFO) when there are no unsent messages in the transmit FIFO. This bit becomes 1 when transmission from the transmit FIFO has been aborted. The TFEST bit becomes 0 (unsent message in transmit FIFO) when there is at least one unsent messages in the transmit FIFO.

Figure 25.15 shows transmit FIFO mailbox operation.

Figure 25.17 Registers C0STR and C1STR

25.1.14.1 RSTST Bit

The RSTST bit becomes 1 when the CAN module enters CAN reset mode.
This bit is 0 when the CAN module is not in CAN reset mode.
Even when the state is changed from CAN reset mode to CAN sleep mode, the RSTST bit remains 1.

25.1.14.2 HLTST Bit

The HLTST bit becomes 1 when the CAN module enters CAN halt mode.
This bit is 0 when the CAN module is not in CAN halt mode.
Even when the state is changed from CAN halt mode to CAN sleep mode, the HLTST bit remains 1.

25.1.14.3 SLPST Bit

The SLPST bit becomes 1 when the CAN module enters CAN sleep mode.
This bit is 0 when the CAN module is not in CAN sleep mode.

25.1.14.4 EPST Bit

The EPST bit becomes 1 when the value of the CiTECR or CiRECR register exceeds 127 and the CAN module enters the error-passive state ($128 \leq$ TEC < 256 or $128 \leq$ REC < 256) (i = 0, 1). This bit is 0 when the CAN module is not in the error-passive state.
TEC indicates the value of the transmit error counter (CiTECR register) and REC indicates the value of the receive error counter (CiRECR register).

25.1.14.5 BOST Bit

The BOST bit becomes 1 when the value of the CiTECR register exceeds 255 and the CAN module enters the bus-off state (TEC $\geq$ 256). This bit is 0 when the CAN module is not in the bus-off state.

25.1.14.6 TRMST Bit

The TRMST bit becomes 1 when the CAN module performs as a transmitter node or enters the bus-off state.
This bit becomes 0 when the CAN module performs as a receiver node or enters the bus-idle state.

25.1.14.7 RECST Bit

The RECST bit becomes 1 when the CAN module performs as a receiver node.
This bit becomes 0 when the CAN module performs as a transmitter node or enters the bus-idle state.

25.1.14.8 NDST Bit

The NDST bit becomes 1 when at least one NEWDATA bit in the CiMCTLj register is 1 regardless of the value of the CiMIER register (j = 0 to 31).
The NDST bit becomes 0 when all NEWDATA bits are 0.

25.1.14.9 SDST Bit

The SDST bit becomes 1 when at least one SENTDATA bit in the CiMCTLj register is 1 regardless of the value of the CiMIER register (i = 0, 1; j = 0 to 31).
The SDST bit becomes 0 when all SENTDATA bits are 0.

25.1.14.10 RFST Bit

The RFST bit is 1 when there are messages in the receive FIFO.
This bit is 0 when the receive FIFO is empty.
This bit becomes 0 when normal mailbox mode is selected.

25.1.14.11 TFST Bit

The TFST bit is 1 when the transmit FIFO is not full.
This bit is 0 when the transmit FIFO is full.
This bit becomes 0 when normal mailbox mode is selected.

25.1.14.12 NMLST Bit

The NMLST bit becomes 1 when at least one MSGLOST bit in the CiMCTLj register is 1 regardless of the value of the CiMIER register.
The NMLST bit becomes 0 when all MSGLOST bits are 0.

25.1.14.13 FMLST Bit

The FMLST bit becomes 1 when the RFMLF bit in the CiRFCR register is 1 regardless of the value of the CiMIER register.
The FMLST bit becomes 0 when the RFMLF bit is 0.

25.1.14.14 TABST Bit

The TABST bit becomes 1 when at least one TRMABT bit in the CiMCTLj register is 1 regardless of the value of the CiMIER register.
The TABST bit becomes 0 when all TRMABT bits are 0.

25.1.14.15 EST Bit

The EST bit becomes 1 when at least one error is detected by the CiEIFR register regardless of the value of the CiEIER register.
This bit becomes 0 when no error is detected by the CiEIFR register.

25.1.15   CANi Mailbox Search Mode Register (CiMSMR) (i = 0, 1)

Note:
1. Write to the CiMSMR register in CAN operation mode or CAN halt mode.

Figure 25.18 Registers C0MSMR and C1MSMR

25.1.15.1 MBSM Bit

Set the MBSM bit to select the search mode for the mailbox search function.
When this bit is 00b, receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA bit in the CiMCTLj register for the normal mailbox and the RFEST bit in the CiRFCR register (j = 0 to 31).
When the MBSM bit is 01b, transmit mailbox search mode is selected. In this mode, the search target is the SENTDATA bit in the CiMCTLj register.
When the MBSM bit is 10b, message lost search mode is selected. In this mode, the search targets are the MSGLOST bit in the CiMCTLj register for the normal mailbox and the RFMLF bit in the CiRFCR register.
When the MBSM bit is 11b, channel search mode is selected. In this mode, the search target is the CiCSSR register.
Refer to 25.1.17 "CANi Channel Search Support Register (CiCSSR) (i = 0, 1)".

25.1.16 CANi Mailbox Search Status Register (CiMSSR) (i = 0, 1)

CANi Mailbox Search Status Register (i = 0, 1)

b7 b6 b5 b4 b3 b2 b1 b0

Symbol	Address	Reset Value

MBNST	Search Result Mailbox Number Status Bit	Search result in each search mode is shown Shown number: 0 to 31	RO
— (b6-b5)	No register bits; the read value is 0		—
SEST	Search Result Status Bit	0: Search result found 1: No search result	RO

Figure 25.19 Registers C0MSSR and C1MSSR

25.1.16.1 MBNST Bit

The MBNST bit shows the smallest mailbox number that is searched in each mode of the CiMSMR register (i = 0, 1).

The result searched in receive mailbox, transmit mailbox, and message lost search modes is updated when:

- The NEWDATA, SENTDATA, or MSGLOST bit for the shown mailbox is set to 0.
- The NEWDATA, SENTDATA, or MSGLOST bit for a higher-priority mailbox is set to 1.

In receive mailbox search and message lost search modes, the receive FIFO (mailbox [28]) is shown when there are messages in the receive FIFO, and there are no unread received messages or lost messages in any of the normal mailboxes (mailboxes [0] to [23]).

In transmit mailbox search mode, the transmit FIFO (mailbox [24]) is not shown.

Table 25.7 lists the operation of MBNST bit in FIFO mailbox mode.

Table 25.7   Operation of MBNST Bit in FIFO Mailbox Mode

MBSM Bit	Mailbox [24] (Transmit FIFO)	Mailbox [28] (Receive FIFO)
00b	"24" is not shown	"28" is shown when no NEWDATA bit for the normal mailbox is set to 1 and there are messages in the receive FIFO
01b		"28" is not shown
10b		"28" is shown when no MSGLOST bit for the normal mailbox is set to 1 and the RFMLF bit is set to 1 in the receive FIFO
11b		"28" is not shown

In channel search mode, the MBNST bit shows the corresponding channel number. After the CiMSSR register is read by a program, the next target channel number is shown.

25.1.16.2 SEST Bit

The SEST bit becomes 1 when no corresponding mailbox is found after searching all mailboxes.

For example, in transmit mailbox search mode, the SEST bit becomes 1 when no SENTDATA bit for mailboxes is 1. The SEST bit becomes 0 when at lease one SENTDATA bit is 1.

When the SEST bit is 1, the value of the MBNST bit is undefined.

25.1.17 CANi Channel Search Support Register (CiCSSR) (i = 0, 1)

	C1CSSR	47B51h	Undefined

Function	Setting Value	RW
When the value of the channel search is input, the channel number is output to the CiMSSR register	Channel value	RW

Notes:
1. Write to the CiCSSR register only when the MBSM bit in the CiMSMR register is 11b (channel search mode).
2. Write to the CiCSSR register in CAN operation mode or CAN halt mode.

Figure 25.20 Registers C0CSSR and C1CSSR

The bits in the CiCSSR register, which are set to 1, are encoded by an 8-to-3 priority encoder (the lower bit position, the higher priority) and shown on the MBNST bits in the CiMSSR register.
The value of the CiMSSR register is updated whenever the CiMSSR register is read.
Figure 25.21 shows the write and read of registers CiCSSR and CiMSSR.
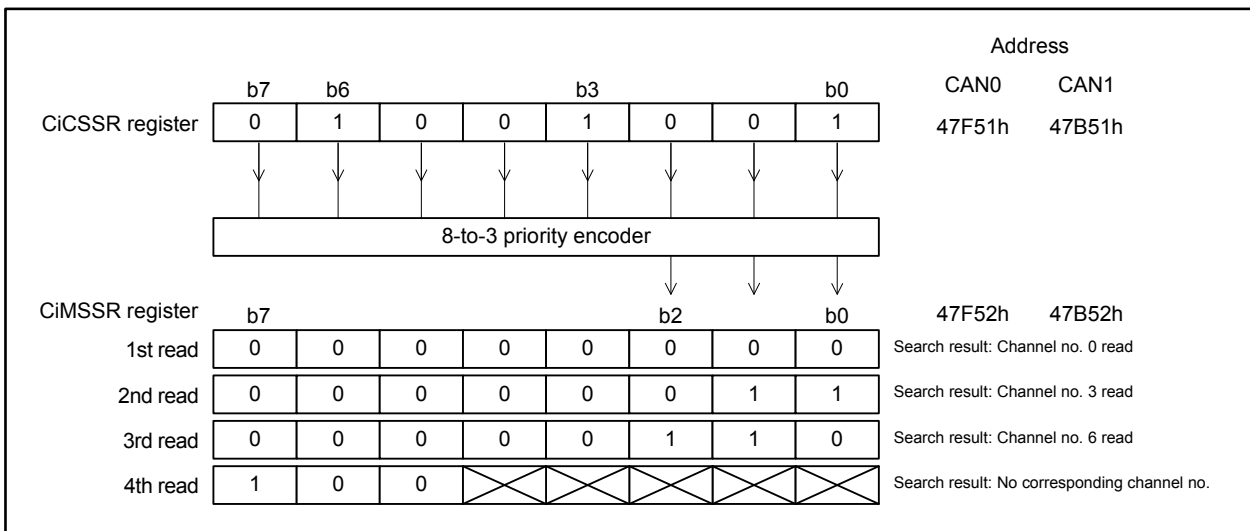

Figure 25.21 Write and Read of Registers CiCSSR and CiMSSR (i = 0, 1)

The value of the CiCSSR register is also updated whenever the CiMSSR register is read. When the CiCSSR register is read, the value before the 8-to-3 priority encoder conversion is read.

25.1.18 CANi Acceptance Filter Support Register (CiAFSR) (i = 0, 1)

CANi Acceptance Filter Support Register (i = 0, 1) [1]

	Symbol	Address	Reset Value
b15 b8 b7 b0	C0AFSR	47F57h-47F56h	Undefined
	C1AFSR	47B57h-47B56h	Undefined

Function	Setting Value	RW
After the standard ID of a received message is written, the value converted for data table search can be read	Standard ID/ converted value	RW

Note:
1. Write to the CiAFSR register in CAN operation mode or CAN halt mode.

Figure 25.22 Registers C0AFSR and C1AFSR

The acceptance filter support unit (ASU) can be used for data table (8 bits $\times$ 256) search. In the data table, all standard IDs created by the user are set to be enabled/disabled in bit units. When the CiAFSR register is written with 16-bit unit data including the SID bit in the CiMBj register, in which a received ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read (j = 0 to 31). The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:
- When the ID to receive cannot be masked by the acceptance filter.
  Example: IDs to receive: 078h, 087h, 111h
- When there are too many IDs to receive and software filtering time is expected to be shortened.

Figure 25.23 shows the write and read of CiAFSR register.

Note:
1. Write the same value as the 16-bit unit data including the SID bit in the CiMBj register.
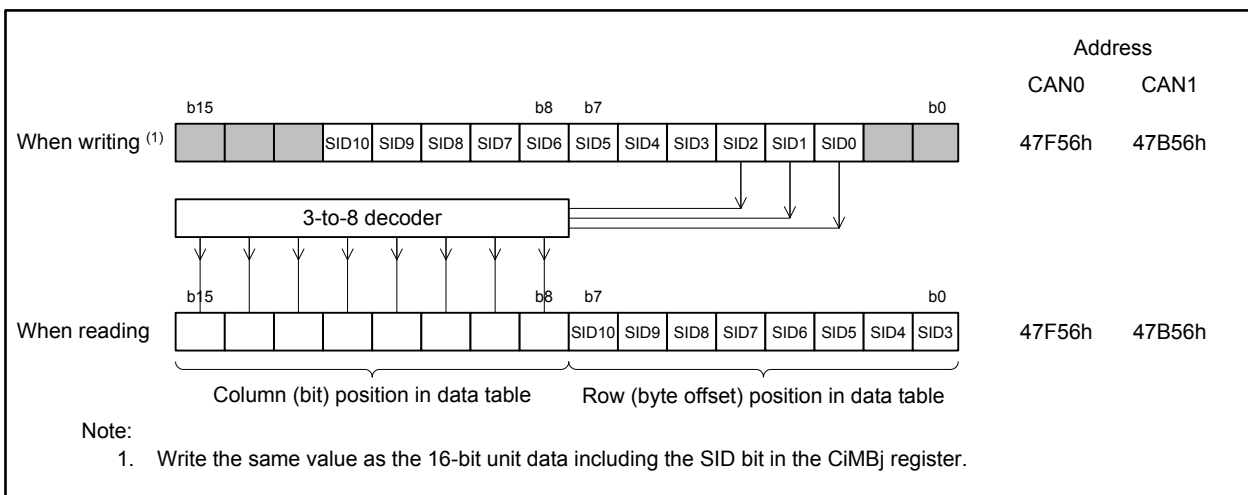

Figure 25.23 Write and Read of CiAFSR Register (i = 0, 1; j = 0 to 31)

25.1.19   CANi Error Interrupt Enable Register (CiEIER) (i = 0, 1)

CANi Error Interrupt Enable Register (i = 0, 1) [1]

Note:
1. Write to the CiEIER register in CAN reset mode.

Figure 25.24 Registers C0EIER and C1EIER

The CiEIER register is used to set the error interrupt enabled/disabled individually for each error interrupt source in the CiEIFR register.

25.1.19.1 BEIE Bit

When the BEIE bit is 0, no error interrupt request is generated even if the BEIF bit in the CiEIFR register is set to 1 (i = 0, 1).
When the BEIE bit is 1, an error interrupt request is generated if the BEIF bit is set to 1.

25.1.19.2 EWIE Bit

When the EWIE bit is 0, no error interrupt request is generated even if the EWIF bit in the CiEIFR register is set to 1.
When the EWIE bit is 1, an error interrupt request is generated if the EWIF bit is set to 1.

25.1.19.3 EPIE Bit

When the EPIE bit is 0, no error interrupt request is generated even if the EPIF bit in the CiEIFR register is set to 1.
When the EPIE bit is 1, an error interrupt request is generated if the EPIF bit is set to 1.

25.1.19.4 BOEIE Bit

When the BOEIE bit is 0, no error interrupt request is generated even if the BOEIF bit in the CiEIFR register is set to 1.
When the BOEIE bit is 1, an error interrupt request is generated if the BOEIF bit is set to 1.

25.1.19.5 BORIE Bit

When the BORIE bit is 0, an error interrupt request is not generated even if the BORIF bit in the CiEIFR register is set to 1.
When the BORIE bit is 1, an error interrupt request is generated if the BORIF bit is set to 1.

25.1.19.6 ORIE Bit

When the ORIE bit is 0, no error interrupt request is generated even if the ORIF bit in the CiEIFR register is set to 1.
When the ORIE bit is 1, an error interrupt request is generated if the ORIF bit is set to 1.

25.1.19.7 OLIE Bit

When the OLIE bit is 0, no error interrupt request is generated even if the OLIF bit in the CiEIFR register is set to 1.
When the OLIE bit is 1, an error interrupt request is generated if the OLIF bit is set to 1.

25.1.19.8 BLIE Bit

When the BLIE bit is 0, no error interrupt request is generated even if the BLIF bit in the CiEIFR register is set to 1.
When the BLIE bit is 1, an error interrupt request is generated if the BLIF bit is set to 1.

25.1.20   CANi Error Interrupt Factor Judge Register (CiEIFR) (i = 0, 1)

CANi Error Interrupt Factor Judge Register (i = 0, 1) [1]

b7 b6 b5 b4 b3 b2 b1 b0	Symbol	Address	Reset Value
	C0EIFR	47F4Dh	00h
	C1EIFR	47B4Dh	00h

Bit Symbol	Bit Name	Function	RW
BEIF	Bus Error Detect Flag	0: No bus error detected 1: Bus error detected	RW
EWIF	Error Warning Detect Flag	0: No error warning detected 1: Error warning detected	RW
EPIF	Error Passive Detect Flag	0: No error passive detected 1: Error passive detected	RW
BOEIF	Bus-off Entry Detect Flag	0: No bus-off entry detected 1: Bus-off entry detected	RW
BORIF	Bus-off Recovery Detect Flag	0: No bus-off recovery detected 1: Bus-off recovery detected	RW
ORIF	Receive Overrun Detect Flag	0: No receive overrun detected 1: Receive overrun detected	RW
OLIF	Overload Frame Transmission Detect Flag	0: No overload frame transmission detected 1: Overload frame transmission detected	RW
BLIF	Bus Lock Detect Flag	0: No bus lock detected 1: Bus lock detected	RW

Note:
1. When writing 0 to these bits by a program, use the MOV instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 to these bits has no effect.

Figure 25.25   Registers C0EIFR and C1EIFR

If an event corresponding to each bit occurs, the corresponding bit in the CiEIFR register is set to 1 regardless of the setting of the CiEIER register.
To set each bit to 0, write 0 by a program. If the set timing occurs simultaneously with the clear timing by the program, the bit becomes 1.

25.1.20.1   BEIF Bit

The BEIF bit becomes 1 when a bus error is detected.

25.1.20.2   EWIF Bit

The EWIF bit becomes 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95.
This bit becomes 1 only when the REC or TEC initially exceeds 95. Thus, if 0 is written to the EWIF bit by a program while the REC or TEC remains greater than 95, this bit does not become 1 until the REC and the TEC go below 95 and then exceed 95 again.

25.1.20.3 EPIF Bit

The EPIF bit becomes 1 when the CAN error state enters the error-passive state (the REC or TEC value exceeds 127).

This bit becomes 1 only when the REC or TEC initially exceeds 127. Thus, if 0 is written to the EPIF bit by a program while the REC or TEC remains greater than 127, this bit does not become 1 until the REC and the TEC go below 127 and then exceed 127 again.

25.1.20.4 BOEIF Bit

The BOEIF bit becomes 1 when the CAN error state enters the bus-off state (the TEC value exceeds 255).

This bit also becomes 1 when the BOM bit in the CiCTLR register is 01b (entry to CAN halt mode automatically at bus-off entry) and the CAN module enters the bus-off state (i = 0, 1).

25.1.20.5 BORIF Bit

The BORIF bit becomes 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions:
 (1) When the BOM bit in the CiCTLR register is 00b
 (2) When the BOM bit is 10b
 (3) When the BOM bit is 11b

The BORIF bit does not become 1 if the CAN module recovers from the bus-off state in the following conditions:
 (1) When the CANM bit in the CiCTLR register is set to 01b (CAN reset mode)
 (2) When the RBOC bit in the CiCTLR register is set to 1 (forced recovery from bus-off)
 (3) When the BOM bit is 01b
 (4) When the BOM bit is 11b and the CANM bit is set to 10b (CAN halt mode) before normal recovery occurs

Table 25.8 lists the operation of bits BOEIF and BORIF according to BOM bit setting value.

Table 25.8   Operation of Bits BOEIF and BORIF According to BOM Bit Setting Value

BOM Bit	BOEIF Bit	BORIF Bit
00b	Becomes 1 when entering the bus-off state	Becomes 1 when recovering from the bus-off state
01b		Does not become 1
10b		Becomes 1 when recovering from the bus-off state
11b		Becomes 1 if normal bus-off recovery occurs before the CANM bit is set to 10b (CAN halt mode)

25.1.20.6 ORIF Bit

The ORIF bit becomes 1 when a receive overrun occurs.

This bit does not become 1 in overwrite mode. In overwrite mode, a reception complete interrupt request is generated if an overwrite condition occurs, thus this bit does not become 1.

In normal mailbox mode, if an overrun occurs in any mailbox from [0] to [31] in overrun mode, this bit is set to 1.

In FIFO mailbox mode, if an overrun occurs in any mailbox from [0] to [23] or the receive FIFO in overrun mode, this bit becomes 1.

25.1.20.7 OLIF Bit

The OLIF bit becomes 1 if the transmitting condition of an overload frame is detected when the CAN module performs transmission or reception.

25.1.20.8 BLIF Bit

The BLIF bit becomes 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode.

After the BLIF bit becomes 1, bus lock can be detected again after either of the following conditions is satisfied:

- After this bit is set to 0 from 1, recessive bits are detected (bus lock is resolved).
- After this bit is set to 0 from 1, the CAN module enters CAN reset mode and then enters CAN operation mode again (internal reset).

25.1.21   CANi Receive Error Count Register (CiRECR) (i = 0, 1)

CANi Receive Error Count Register (i = 0, 1)

b7   b0

Symbol	Address	Reset Value

C1RECR	47B4Eh	00h

Function	Counter Value	RW
Receive error count function The CiRECR register increments or decrements the counter value according to the error status of the CAN module during reception	00h to FFh [1]	RO

Note:
1. The value in the bus-off state is undefined.
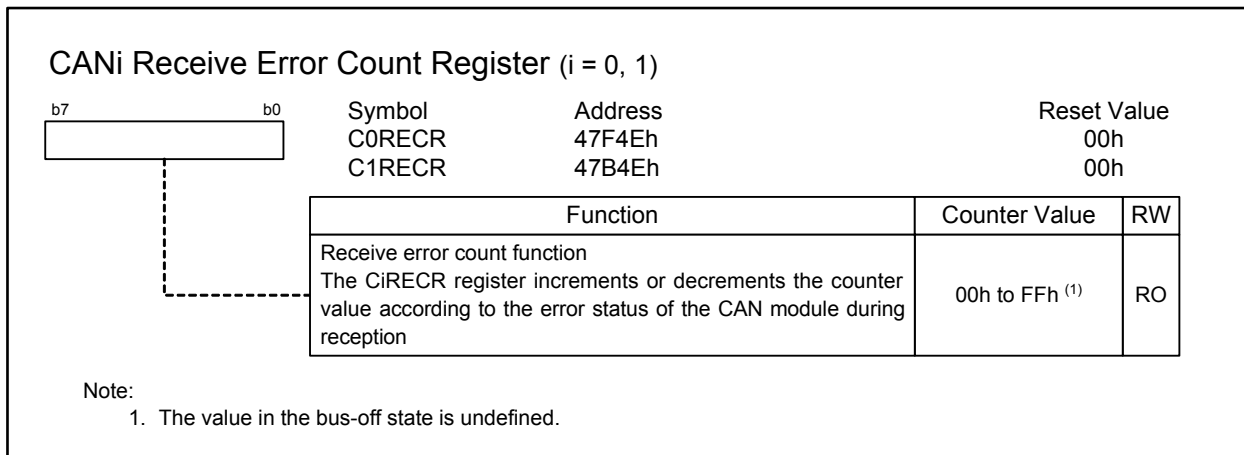

Figure 25.26   Registers C0RECR and C1RECR

The CiRECR register indicates the value of the receive error counter.
Refer to the CAN Specification (ISO 11898-1) for the increment/decrement conditions of the receive error counter.

25.1.22 CANi Transmit Error Count Register (CiTECR) (i = 0, 1)

CANi Transmit Error Count Register (i = 0, 1)

		b7	b0

	Symbol	Address	Reset Value
	C0TECR	47F4h	00h
	C1TECR	47B4h	00h

Function	Counter Value	RW
Transmit error count function The CiTECR register increments or decrements the counter value according to the error status of the CAN module during transmission	00h to FFh [1]	RO

Note:
   1. The value in the bus-off state is undefined.
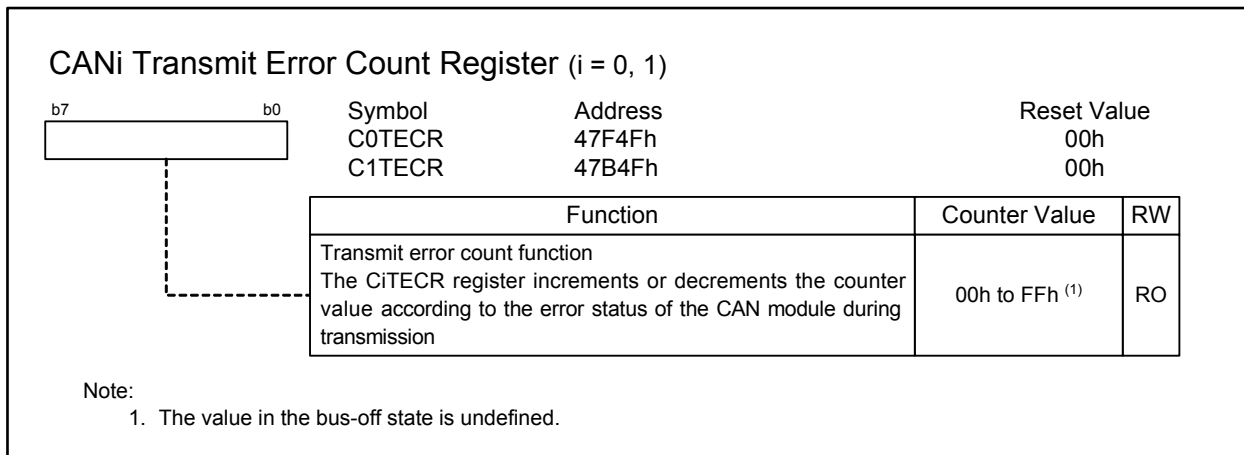

Figure 25.27 Registers C0TECR and C1TECR

The CiTECR register indicates the value of the TEC error counter.
Refer to the CAN Specification (ISO 11898-1) for the increment/decrement conditions of the transmit error counter.

25.1.23   CANi Error Code Store Register (CiECSR) (i = 0, 1)

CANi Error Code Store Register (i = 0, 1)

Symbol	Address	Reset Value
C0ECSR	47F50h	00h
C1ECSR	47B50h	00h

b7 b6 b5 b4 b3 b2 b1 b0

Bit Symbol	Bit Name	Function	RW
SEF	Stuff Error Flag [1, 2]	0: No stuff error detected 1: Stuff error detected	RW
FEF	Form Error Flag [1, 2]	0: No form error detected 1: Form error detected	RW
AEF	ACK Error Flag [1, 2]	0: No ACK error detected 1: ACK error detected	RW
CEF	CRC Error Flag [1, 2]	0: No CRC error detected 1: CRC error detected	RW
BE1F	Bit Error (recessive) Flag [1, 2]	0: No bit error detected 1: Bit error (recessive) detected	RW
BE0F	Bit Error (dominant) Flag [1, 2]	0: No bit error detected 1: Bit error (dominant) detected	RW
ADEF	ACK Delimiter Error Bit [1, 2]	0: No ACK delimiter error detected 1: ACK delimiter error detected	RW
EDPM	Error Display Mode Select Bit [3]	0: Output of first detected error code [4] 1: Output of accumulated error code	RW

Notes:
1. Writing 1 to this bit has no effect.
2. When writing 0 to bits SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF by a program, use the MOV instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.
3. Write to the EDPM bit in CAN reset mode or CAN halt mode.
4. If more than one error condition is detected simultaneously, all corresponding bits are set to 1.

Figure 25.28 Registers C0ECSR and C1ECSR

The CiECSR register can be used to monitor whether an error has occurred on the CAN bus. Refer to the CAN Specification (ISO 11898-1) to check the generation conditions of each error.
To set each bit except the EDPM bit to 0, write 0 by a program. If the timing at which each bit is set to 1 and the timing at which is written by a program are the same, the relevant bit is set to 1.

25.1.23.1   SEF Bit
The SEF bit becomes 1 when a stuff error is detected.

25.1.23.2   FEF Bit
The FEF bit becomes 1 when a form error is detected.

25.1.23.3   AEF Bit
The AEF bit becomes 1 when an ACK error is detected.

25.1.23.4 CEF Bit

The CEF bit becomes 1 when a CRC error is detected.

25.1.23.5 BE1F Bit

The BE1F bit becomes 1 when a recessive bit error is detected.

25.1.23.6 BE0F Bit

The BE0F bit becomes 1 when a dominant bit error is detected.

25.1.23.7 ADEF Bit

The ADEF bit becomes 1 when a form error is detected with the ACK delimiter during transmission.

25.1.23.8 EDPM Bit

The EDPM bit selects the output mode of the CiECSR register (i = 0, 1).
When this bit is set to 0, the CiECSR register outputs the first error code.
When this bit is set to 1, the CiECSR register outputs the accumulated error code.

25.1.24 CANi Time Stamp Register (CiTSR) (i = 0, 1)

CANi Time Stamp Register (i = 0, 1) [1]

b15	b8 b7	b0	Symbol	Address	Reset Value

Symbol   Address   Reset Value
C0TSR   47F55h-47F54h   0000h
C1TSR   47B55h-47B54h   0000h

Function	Counter Value	RW
Free-running counter value for the time stamp function	0000h to FFFFh	RO

Note:
1. Read the CiTSR register in 16-bit units.
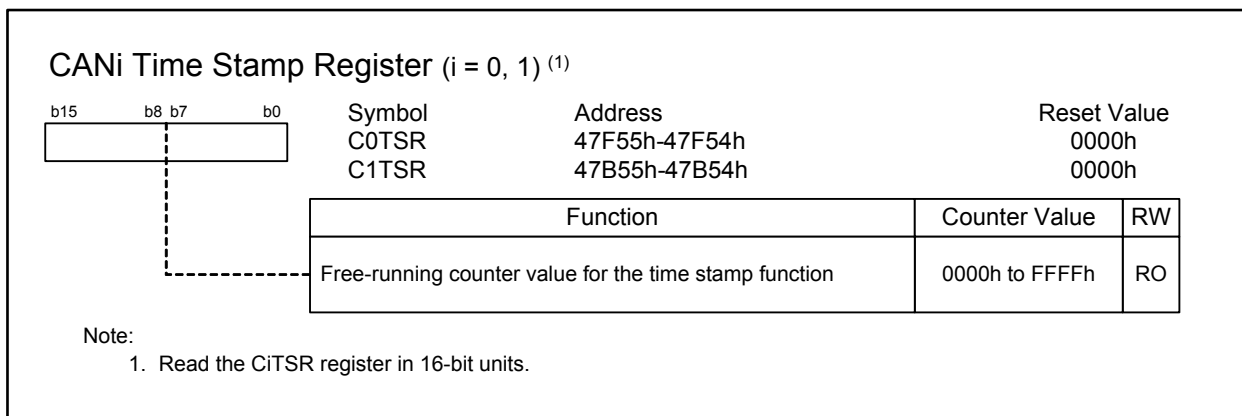

Figure 25.29 Registers C0TSR and C1TSR

When the CiTSR register is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read.
The value of the time stamp counter reference clock is a multiple of 1 bit time, as configured by the TSPS bit in the CiCTLR register.
The time stamp counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode.
The time stamp counter value is stored to TSL and TSH in the CiMBj register when a received message is stored in a receive mailbox (j = 0 to 31).

25.1.25 CANi Test Control Register (CiTCR) (i = 0, 1)

CANi Test Control Register (i = 0, 1) [1]

— (b7-b3)	Reserved	Should be written with 0	RW

Note:
1. Write to the CiTCR register only in CAN halt mode.

Figure 25.30 Registers C0TCR and C1TCR

25.1.25.1 TSTE Bit

When the TSTE bit is set to 0, CAN test mode is disabled.
When this bit is set to 1, CAN test mode is enabled.

25.1.25.2 TSTM Bit

The TSTM bit selects the CAN test mode.
The details of each CAN test mode are described from the next page.

25.1.25.3   Listen Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In listen only mode, the CAN node is able to receive valid data frames and valid remote frames. It sends only recessive bits on the CAN bus and the protocol controller is not required to send the ACK bit, overload flag, or active error flag.

Listen only mode can be used for baud rate detection.

Do not request transmission from any mailboxes in this mode.

Figure 25.31 shows the connection when listen only mode is selected.
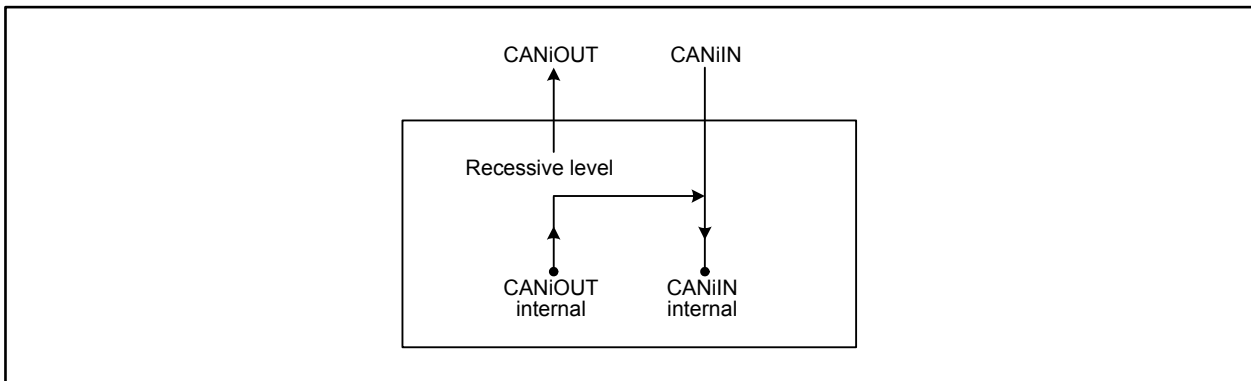

Figure 25.31 Connection when Listen Only Mode is Selected (i = 0, 1)

25.1.25.4   Self Test Mode 0 (External Loop Back)

Self test mode 0 is provided for CAN transceiver tests.

In this mode, the protocol controller treats its own transmitted messages as messages received via the CAN transceiver and stores them into a receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

Connect the CANiOUT/CANiIN pins to the transceiver (i = 0, 1).

Figure 25.32 shows the connection when self test mode 0 is selected.
Figure 25.32 Connection when Self Test Mode 0 is Selected (i = 0, 1)

25.1.25.5 Self Test Mode 1 (Internal Loop Back)

Self test mode 1 is provided for self test functions.

In this mode, the protocol controller treats its transmitted messages as received messages and stores them into a receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self test mode 1, the protocol controller performs an internal feedback from the internal CANiOUT pin to the internal CANiIN pin (i = 0, 1). The input value of the external CANiIN pin is ignored. The external CANiOUT pin outputs only recessive bits. The CANiOUT/CANiIN pins do not need to be connected to the CAN bus or any external device.

Figure 25.33 shows the connection when self test mode 1 is selected.
Figure 25.33 Connection when Self Test Mode 1 is Selected (i = 0, 1)

25.2   Operating Modes

The CAN module has the following four operating modes:
- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 25.34 shows the transition between CAN operating modes.

CANM, SLPM, BOM, and RBOC: Bits in the CiCTLR register

Notes:
1. The transition timing from the bus-off state to CAN halt mode depends on the setting of the BOM bit.
   - When the BOM bit is 01b, the state transition timing is immediately after entering the bus-off state.
   - When the BOM bit is 10b, the state transition timing is at the end of the bus-off state.
   - When the BOM bit is 11b, the state transition timing is at the setting of the CANM bit to 10b (CAN halt mode).
2. Write only to the SLPM bit to exit/set CAN sleep mode.
3. The CAN module does not enter CAN Halt mode while the CAN bus is locked in dominant state. Enter CAN reset mode instead.

Figure 25.34 Transition between CAN Operating Modes (i = 0, 1)

25.2.1   CAN Reset Mode

CAN reset mode is provided for CAN communication configuration.
When the CANM bit in the CiCTLR register is set to 01b, the CAN module enters CAN reset (i = 0, 1).
Then the RSTST bit in the CiSTR register becomes 1. Do not change the CANM bit until the RSTST bit
becomes 1.
Configure the CiBCR register before exiting CAN reset mode and entering any other mode.

The following registers are initialized to their reset values after entering CAN reset mode and their
initialized values are retained during CAN reset mode:
- CiMCTLj register (j = 0 to 31)
- CiSTR register (except bits SLPST and TFST)
- CiEIFR register
- CiRECR register
- CiTECR register
- CiTSR register
- CiMSSR register
- CiMSMR register
- CiRFCR register
- CiTFCR register
- CiTCR register
- CiECSR register (except EDPM bit)

The previous values of the following registers are retained after entering CAN reset mode:
- CiCLKR register
- CiCTLR register
- CiSTR register (bits SLPST and TFST)
- CiMIER register
- CiEIER register
- CiBCR register
- CiCSSR register
- CiECSR register (EDPM bit only)
- CiMBj register
- Registers CiMKR0 to CiMKR7
- Registers CiFIDCR0 and CiFIDCR1
- CiMKIVLR register
- CiAFSR register
- CiRFPCR register
- CiTFPCR register

25.2.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CANM bit in the CiCTLR register is set to 10b, CAN halt mode is selected (i = 0, 1). Then the HLTST bit in the CiSTR register becomes 1. Do not change the CANM bit until the HLTST bit becomes 1.

Refer to Table 25.9 "Operation in CAN Reset Mode and CAN Halt Mode" regarding the state transition conditions when transmitting or receiving.

All registers except bits RSTST, HLTST, and SLPST in the CiSTR register remain unchanged when the CAN module enters CAN halt mode.

Do not change registers CiCLKR, CiCTLR (except bits CANM and SLPM), and CiEIER in CAN halt mode. The CiBCR register can be changed in CAN halt mode only when listen only mode is selected to use with automatic bit rate detection.

Table 25.9   Operation in CAN Reset Mode and CAN Halt Mode

Mode	Receiver	Transmitter	Bus-off
CAN reset mode	CAN module enters CAN reset mode without waiting for the end of message reception	CAN module enters CAN reset mode after waiting for the end of message transmission [1, 4]	CAN module enters CAN reset mode without waiting for the end of bus-off recovery

CAN halt mode	CAN module enters CAN halt mode after waiting for the end of message reception [2, 3]	CAN module enters CAN halt mode after waiting for the end of message transmission [1, 2, 4]	- When the BOM bit is 00b
			  A halt request from a program will be acknowledged only after bus-off recovery
			- When the BOM bit is 01b
			  CAN module automatically enters CAN halt mode without waiting for the end of bus-off recovery (regardless of a halt request from a program)
			- When the BOM bit is 10b
			  CAN module automatically enters CAN halt mode after waiting for the end of bus-off recovery (regardless of a halt request from a program)
			- When the BOM bit is 11b
			  CAN module enters CAN halt mode (without waiting for the end of bus-off recovery) if a halt is requested by a program during bus-off

BOM bit: Bit in the CiCTLR register (i = 0, 1)

Notes:

1. If several messages are requested to be transmitted, mode transition occurs after the completion of the first message transmission. When CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.

2. If the CAN bus is locked in dominant state, the program can detect this state by monitoring the BLIF bit in the CiEIFR register. The CAN module does not enter CAN Halt mode while the CAN bus is locked in dominant state. Enter CAN reset mode instead.

3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN mode transits to CAN halt mode. However, the CAN module does not enter CAN Halt mode when the CAN bus is locked in dominant state.

4. If a CAN bus error or arbitration lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module enters the requested operating mode. However, the CAN module does not enter CAN Halt mode when the CAN bus is locked in dominant state.

25.2.3   CAN Sleep Mode

CAN sleep mode is used for reducing current consumption by stopping the clock supply to the CAN module. After a MCU reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in the CiCTLR register is set to 1, the CAN module enters CAN sleep mode (i = 0, 1). Then the SLPST bit in the CiSTR register becomes 1. Do not change the value of the SLPM bit until the SLPST bit becomes 1. Other registers remain unchanged when the MCU enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Only the SLPM bit can be changed during CAN sleep mode. Do not change other bits or registers than the CiCTLR register. Read operations are still allowed.
When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

25.2.4   CAN Operation Mode (Excluding Bus-off State)

CAN operation mode is used for CAN communication.
When the CANM bit in the CiCTLR register is set to 00b, the CAN module enters CAN operation mode (i = 0, 1).
Then bits RSTST and HLTST in the CiSTR register become 0. Do not change the value of the CANM bit until these bits become 0.

When 11 consecutive recessive bits are detected after entering CAN operation mode, the CAN module is in the following states:
- The CAN module becomes an active node on the network that enables transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module may be in one of the following three submodes, depending on the status of the CAN bus:
- Idle mode: Transmission or reception is not being performed.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module may receive its own message simultaneously when self test mode 0 (TSTM bits in the CiTCR register are 10b) or self test mode 1 (TSTM bits are 11b) is selected.

Figure 25.35 shows the submode in CAN operation mode.
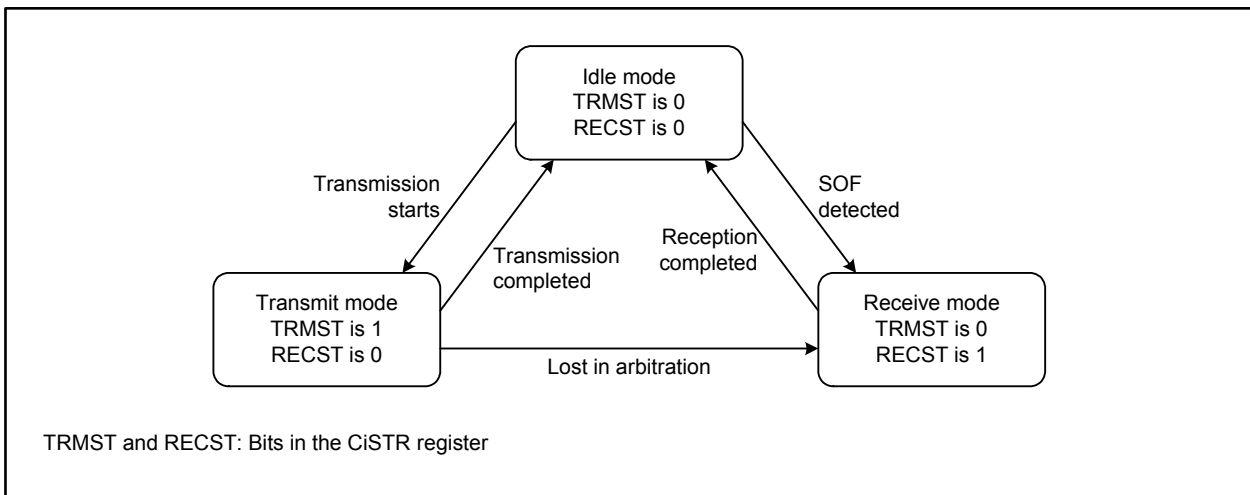

Figure 25.35 Submode in CAN Operation Mode (i = 0, 1)

25.2.5   CAN Operation Mode (Bus-off State)

The CAN module enters the bus-off state according to the increment/decrement rules for the transmit/ error counters in the CAN Specifications.

The following cases apply when recovering from the bus-off state. When the CAN module is in the bus-off state, the values of the associated registers, except registers CiSTR, CiEIFR, CiRECR, CiTECR, and CiTSR, remain unchanged (i = 0, 1).

(1)   When the BOM bit in the CiCTLR register is 00b (normal mode)

The CAN module enters the error-active state after it has completed the recovery from the bus-off state and CAN communication is enabled. The BORIF bit in the CiEIFR register becomes 1 (bus-off recovery detected) at this time.

(2)   When the RBOC bit in the CiCTLR register is set to 1 (forced recovery from bus-off)

The CAN module enters the error-active state when it is in the bus-off state and the RBOC bit is set to 1. CAN communication is enabled again after 11 consecutive recessive bits are detected. The BORIF bit does not become 1 at this time.

(3)   When the BOM bit is 01b (entry to CAN halt mode automatically at bus-off entry)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF bit does not become 1 at this time.

(4)   When the BOM bit is 10b (entry to CAN halt mode automatically at bus-off end)

The CAN module enters CAN halt mode when it has completed the recovery from bus-off. The BORIF bit becomes 1 at this time.

(5)   When the BOM bit is 11b (entry to CAN halt mode by a program) and the CANM bit in the CiCTLR register is set to 10b (CAN halt mode) during the bus-off state

The CAN module enters CAN halt mode when it is in the bus-off state and the CANM bit is set to 10b (CAN halt mode). The BORIF bit does not become 1 at this time.

If the CANM bit is not set to 10b during bus-off, the same behavior as (1) applies.

25.3   CAN Communication Speed Configuration

The following description explains about the CAN communication speed configuration.

25.3.1   CAN Clock Configuration

This group has a CAN clock selector.
The CAN clock can be configured by setting the CCLKS bit in the CiCLKR register and the BRP bit in the CiBCR register (i = 0, 1).
Figure 25.36 shows the block diagram of CAN clock generator.
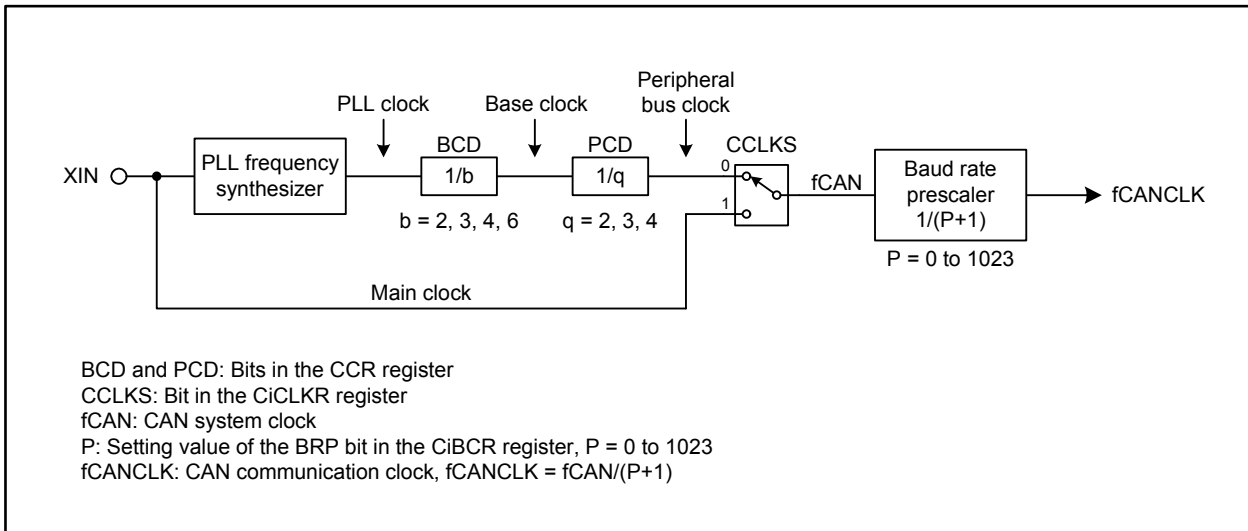

Figure 25.36 Block Diagram of the CAN Clock Generator (i = 0, 1)

25.3.2   Bit Timing Configuration

The bit time is a single bit time for transmitting/receiving a message and consists of the three segments in the figure below.
Figure 25.37 shows the bit timing.
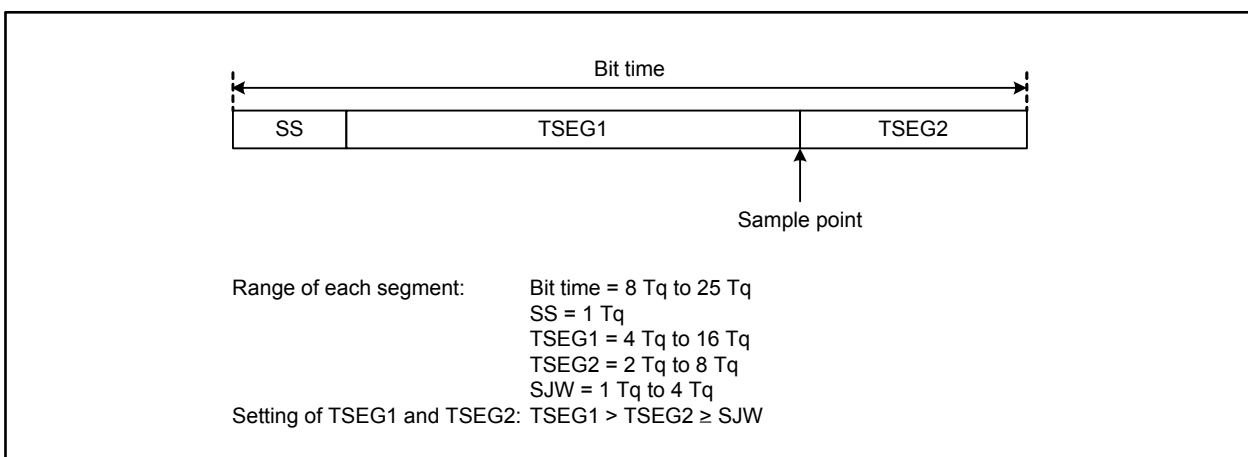

Figure 25.37 Bit Timing

25.3.3   Bit rate

The bit rate depends on the CAN clock (fCAN), the divisor of the baud rate prescaler, and the number of Tq of 1 bit time.

$$\text{Bit rate[bps]} = \frac{fCAN}{\text{Baud rate prescaler division value}^{(1)} \times \text{number of Tq of 1 bit time}} = \frac{fCANCLK}{\text{Number of Tq of 1 bit time}}$$

Note:
1.   Divisor of the baud rate prescaler = P + 1 (P = 0 to 1023)
      P: Setting value of the BRP bit in the CiBCR register (i = 0, 1)

Table 25.10 lists bit rate examples.

Table 25.10   Bit Rate Examples

fCAN	32 MHz		24 MHz		20 MHz		16 MHz		8 MHz	
Bit Rate	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1

25.4 Mailbox and Mask Register Structure

There are 32 mailboxes with the same structure.
Figure 25.38 shows the structure of registers C0MBj to C1MBj (j = 0 to 31).
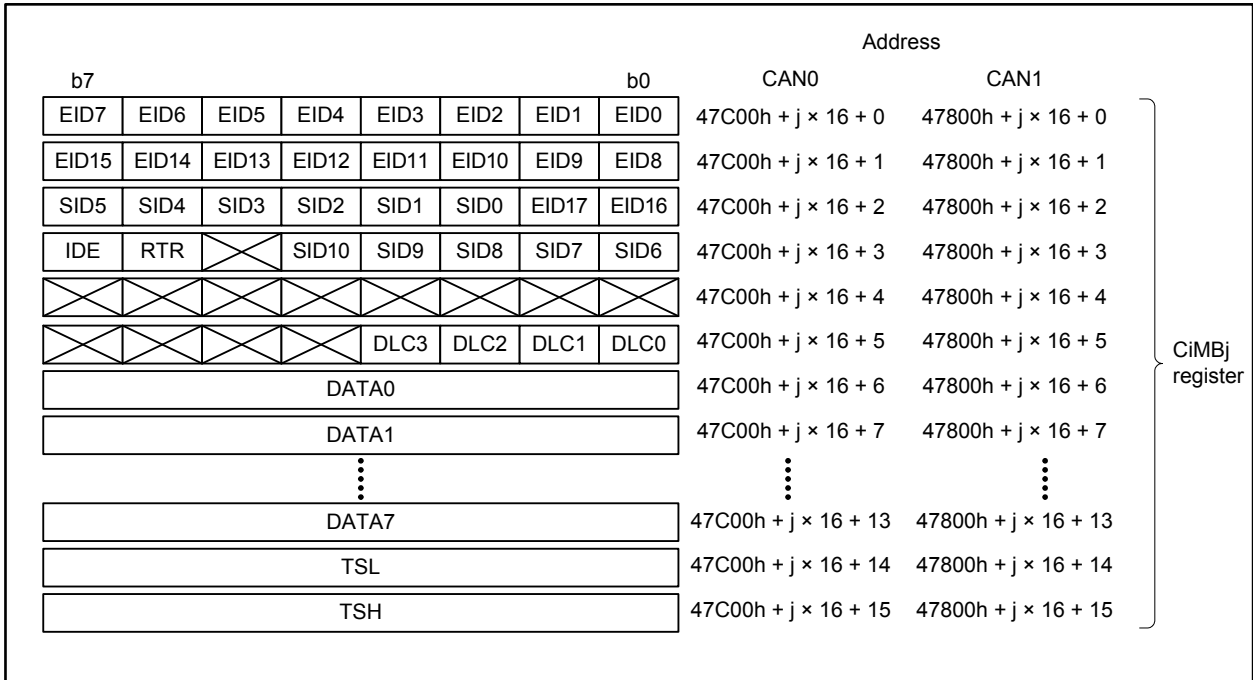

Figure 25.38 Structure of Registers C0MBj to C1MBj (i = 0, 1; j = 0 to 31)

There are eight mask registers with the same structure.
Figure 25.39 shows the structure of registers C0MKRk to C1MKRk (k = 0 to 7).
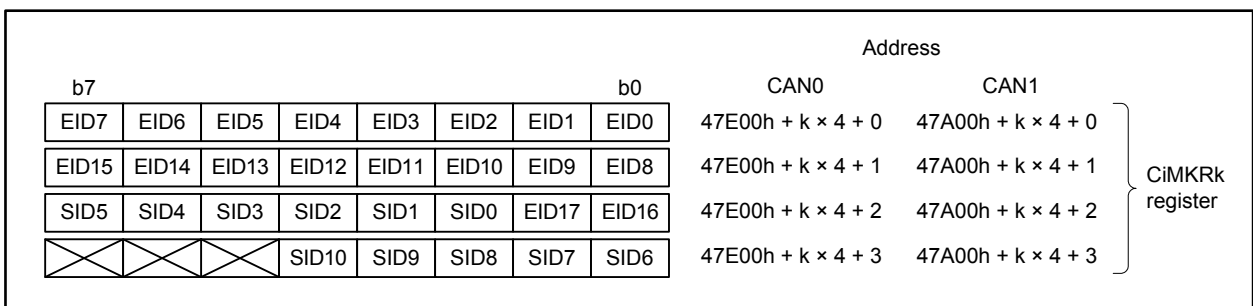

Figure 25.39 Structure of Registers C0MKRk to C1MKRk (i = 0, 1; k = 0 to 7)

There are two FIFO received ID compare registers with the same structure.
Figure 25.40 shows the structure of registers C0FIDCRn to C1FIDCRn (n = 0, 1).

								Address		
									CAN0	CAN1
b7							b0			
EID7	EID6	EID5	EID4	EID3	EID2	EID1	EID0	47E20h + n × 4 + 0	47A20h + n × 4 + 0	
EID15	EID14	EID13	EID12	EID11	EID10	EID9	EID8	47E20h + n × 4 + 1	47A20h + n × 4 + 1	CiFIDCRn register
SID5	SID4	SID3	SID2	SID1	SID0	EID17	EID16	47E20h + n × 4 + 2	47A20h + n × 4 + 2

Figure 25.40 Structure of Registers C0FIDCRn to C1FIDCRn (i = 0, 1; n = 0, 1)

25.5   Acceptance Filtering and Masking Function

Acceptance filtering allows the user to receive messages with a specified range of multiple IDs for mailboxes.

Registers CiMKR0 to CiMKR7 can perform masking of the standard ID and the extended ID of 29 bits (i = 0, 1).

- The CiMKR0 register corresponds to mailboxes [0] to [3].
- The CiMKR1 register corresponds to mailboxes [4] to [7].
- The CiMKR2 register corresponds to mailboxes [8] to [11].
- The CiMKR3 register corresponds to mailboxes [12] to [15].
- The CiMKR4 register corresponds to mailboxes [16] to [19].
- The CiMKR5 register corresponds to mailboxes [20] to [23].
- The CiMKR6 register corresponds to mailboxes [24] to [27] in normal mailbox mode, and receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.
- The CiMKR7 register corresponds to mailboxes [28] to [31] in normal mailbox mode, and receive FIFO mailboxes [28] to [31] in FIFO mailbox mode.

The CiMKIVLR register disables acceptance filtering individually for each mailbox.

The IDE bit in the CiMBj register is enabled when the IDFM bit in the CiCTLR register is 10b (mixed ID mode) (j = 0 to 31).

The RTR bit in the CiMBj register selects a data frame or a remote frame.

In FIFO mailbox mode, normal mailboxes (mailboxes [0] to [23]) use the single corresponding register among registers CiMKR0 to CiMKR5 for acceptance filtering. Receive FIFO mailboxes (mailboxes [28] to [31]) use two registers CiMKR6 and CiMKR7 for acceptance filtering.

Also, the receive FIFO uses registers CiFIDCR0 and CiFIDCR1 for ID comparison. Bits EID, SID, RTR, and IDE in registers CiMB28 to CiMB31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two ID-mask sets, two ranges of IDs can be received into the receive FIFO.

The CiMKIVLR register is disabled for the receive FIFO.

If both the settings for standard ID and extended ID are set in the IDE bits in registers CiFIDCR0 and CiFIDCR1 individually, both ID formats are received.

If both setting of data frame and remote frame are set in the RTR bits in registers CiFIDCR0 and CiFIDCR1 individually, both the data and remote frames are received.

When a combination of two ranges of IDs is not necessary, set the same mask value and the same ID into both of the FIFO ID/mask register sets.

Figure 25.41 shows the mask registers and their corresponding mailboxes, and Figure 25.42 shows acceptance filtering.
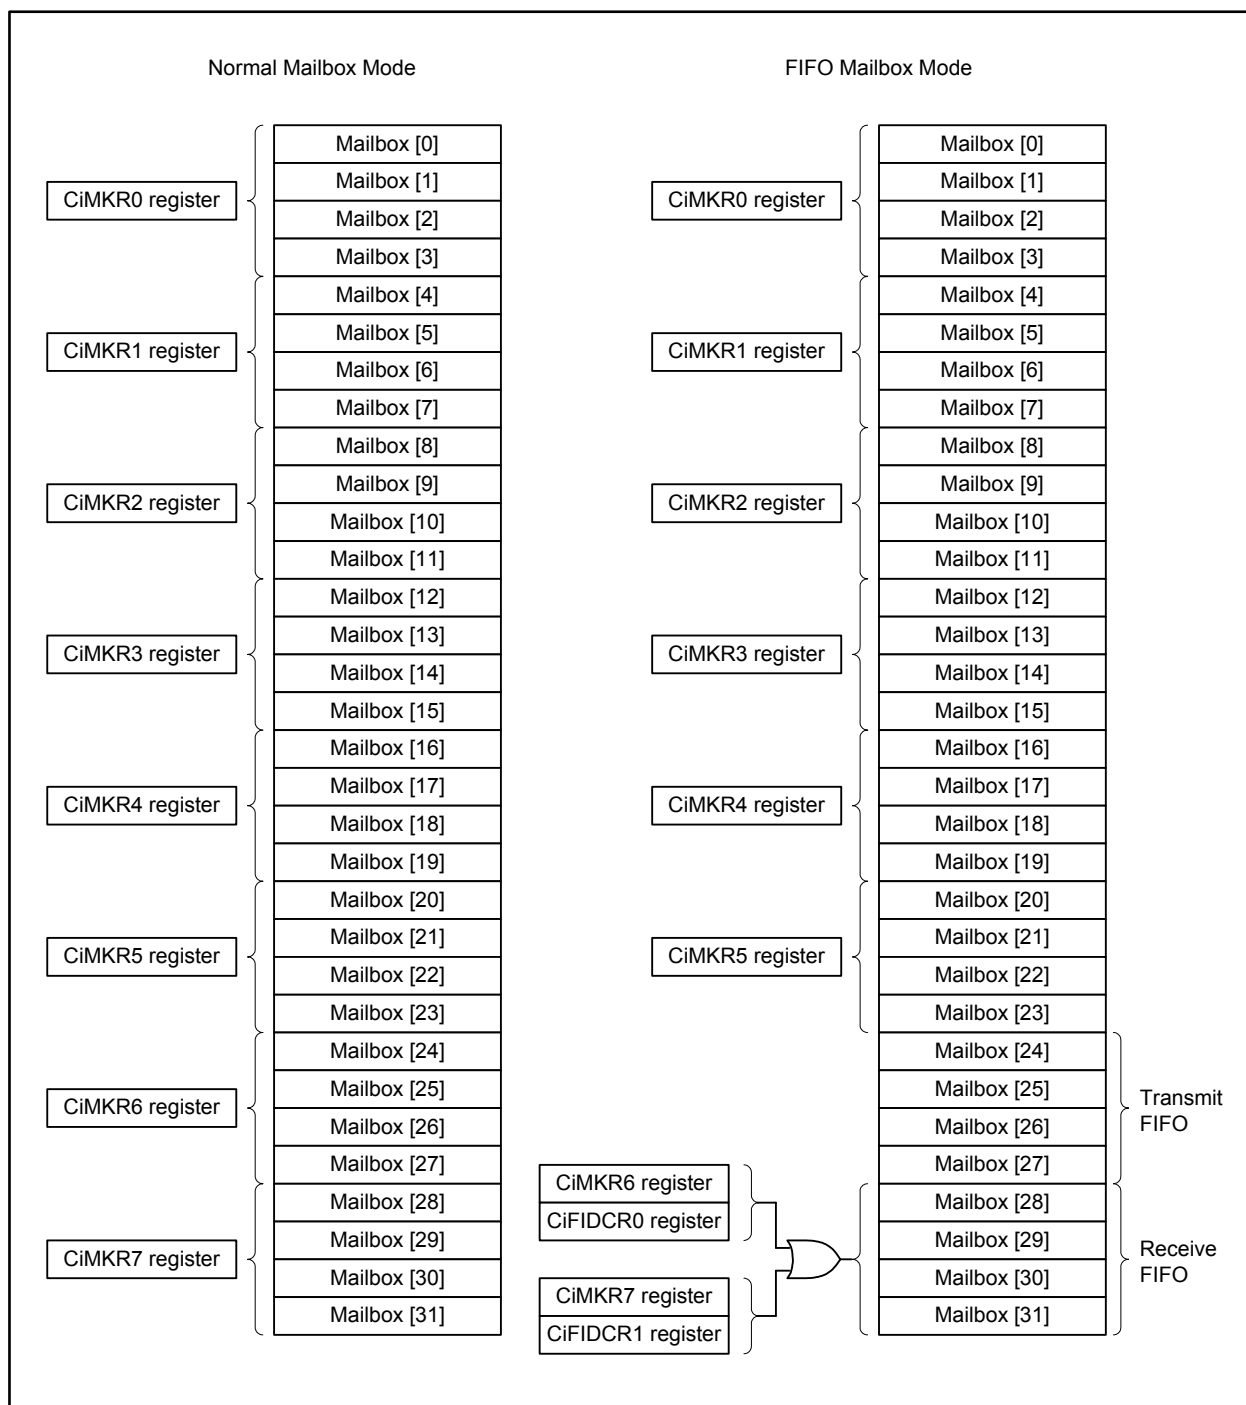

Figure 25.41 Mask Registers and Their Corresponding Mailboxes (i = 0, 1)
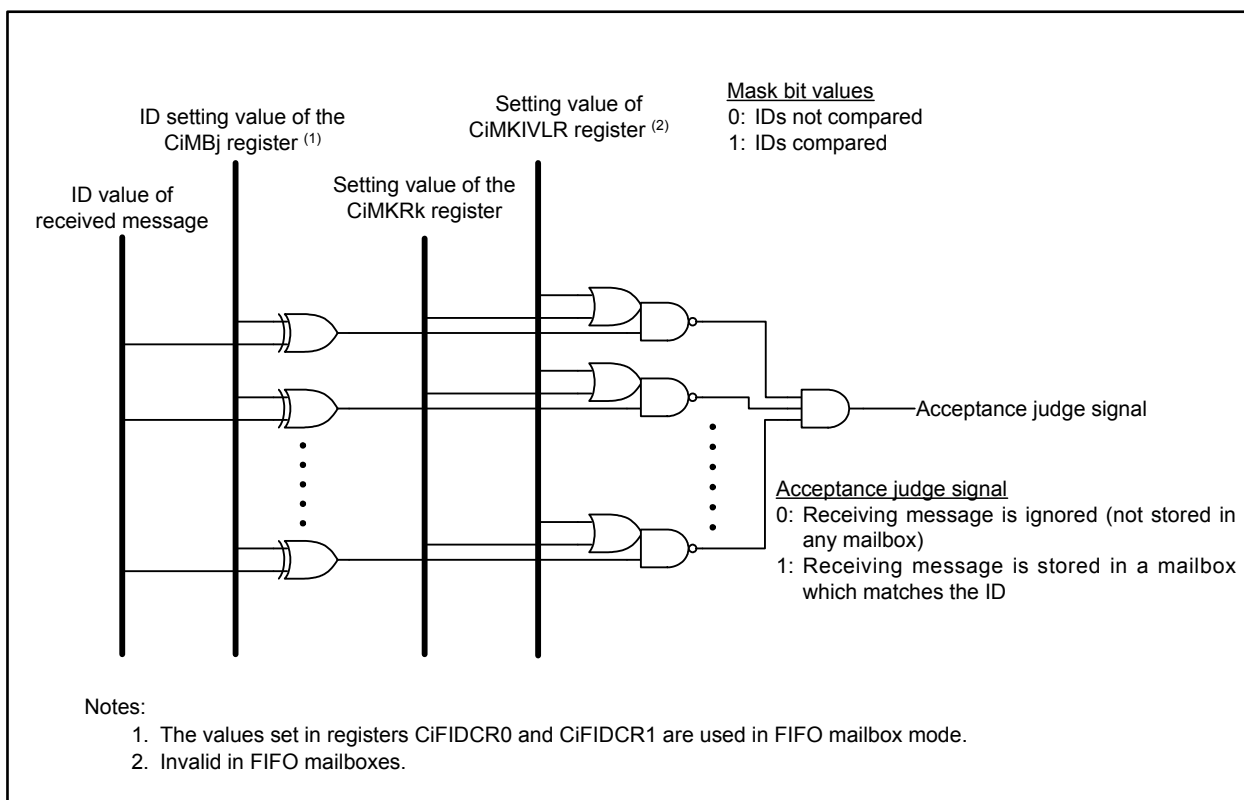

Figure 25.42 Acceptance Filtering (i = 0, 1; j = 0 to 31; k = 0 to 7)

25.6   Reception and Transmission

Table 25.11 lists the CAN communication mode configuration.

Table 25.11   Configuration for CAN Reception Mode and Transmission Mode

TRMREQ	RECREQ	ONESHOT	Communication Mode of Mailbox
0	0	0	Mailbox disabled or transmission being aborted
0	0	1	Configurable only when transmission or reception from a mailbox (programmed in one-shot mode) is aborted
0	1	0	Configured as a receive mailbox for a data frame or a remote frame
0	1	1	Configured as a one-shot receive mailbox for a data frame or a remote frame
1	0	0	Configured as a transmit mailbox for a data frame or a remote frame
1	0	1	Configured as a one-shot transmit mailbox for a data frame or a remote frame
1	1	0	Do not set
1	1	1	Do not set

TRMREQ, RECREQ, and ONESHOT: Bits in the CiMCTLj register (i = 0, 1; j = 0 to 31)

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, note the following:
   (1) Before a mailbox is configured as a receive mailbox or a one-shot receive mailbox, set the CiMCTLj register to 00h (i = 0, 1; j = 0 to 31).
   (2) A received message is stored into the first mailbox that matches the condition according to the result of receive mode configuration and acceptance filtering. Upon deciding which mailbox stores the received message, the mailbox with the smaller number has higher priority.
   (3) When transmitting a message in CAN operation mode, the CAN module does not receive the message even if its ID matches the ID of its own mailbox for reception. However, the CAN module receives the message and returns an ACK in self test mode.

When a mailbox is configured as a transmit mailbox or a one-shot transmit mailbox, note the following:
   (1) Before a mailbox is configured as a transmit mailbox or one-shot transmit mailbox, ensure that the CiMCTLj register is 00h and that there is no pending abort process.

25.6.1   Reception

Figure 25.43 shows an operation example of data frame reception in overwrite mode.
This example shows the operation of overwriting the first message when the CAN module receives two
consecutive CAN messages that match the receiving conditions of the CiMCTL0 register (i = 0, 1).
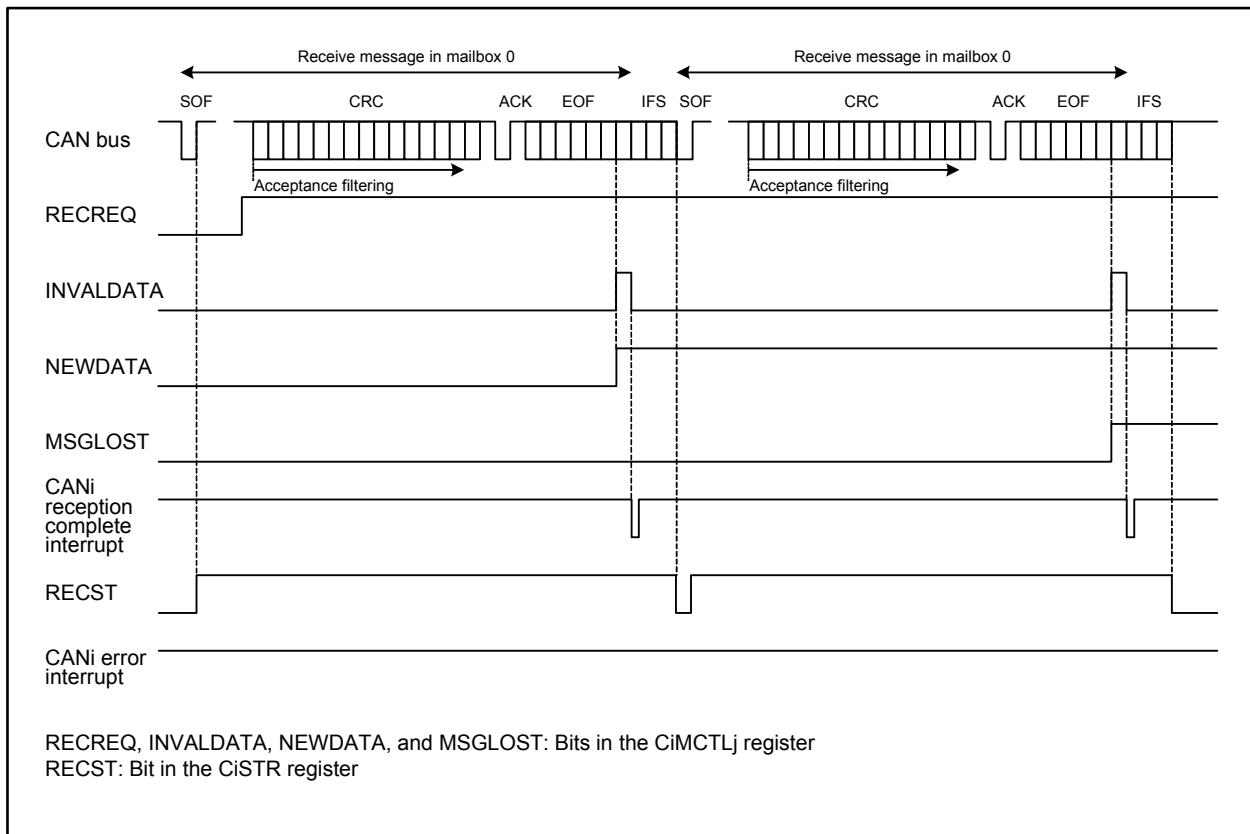

Figure 25.43 Operation Example of Data Frame Reception in Overwrite Mode (i = 0, 1; j = 0 to 31)

(1) When an SOF is detected on the CAN bus, the RECST bit in the CiSTR register becomes 1
    (reception in progress) if the CAN module has no message ready to start transmission.
(2) The acceptance filter procedure starts at the beginning of the CRC field to select the receive
    mailbox.
(3) After a message has been received, the NEWDATA bit in the CiMCTLj register for the receive
    mailbox becomes 1 (new data being updated/stored in the mailbox) (j = 0 to 31). Simultaneously,
    the INVALDATA bit in the CiMCTLj register becomes 1 (message is being updated), and then the
    INVALDATA bit becomes 0 (message valid) again after the complete message is transferred to the
    mailbox.
(4) When the interrupt enable bit in the CiMIER register for the receive mailbox is 1 (interrupt enabled),
    the CANi reception complete interrupt request is generated. This interrupt occurs when the
    INVALDATA bit becomes 0.
(5) After reading the message from the mailbox, the NEWDATA bit needs to be set to 0 by a program.
(6) In overwrite mode, if the next CAN message has been received into a mailbox whose NEWDATA
    bit is still set to 1, the MSGLOST bit in the CiMCTLj register becomes 1 (message has been
    overwritten). The new received message is transferred to the mailbox. The CANi reception
    complete interrupt request is generated the same as in (4).

Figure 25.44 shows an operation example of data frame reception in overrun mode.

This example shows the operation of overrunning the second message when the CAN module receives two consecutive CAN messages that match the receiving conditions of the CiMCTL0 register (i = 0, 1).
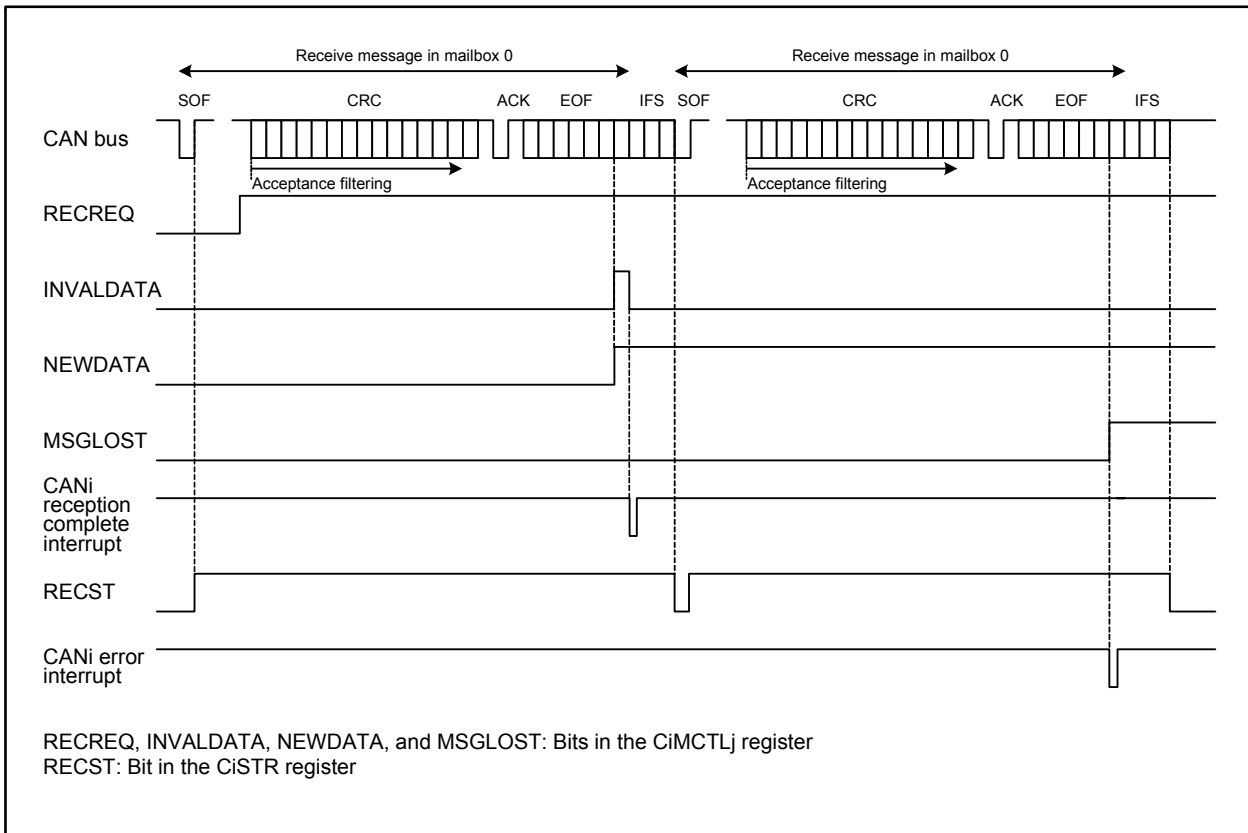

Figure 25.44 Operation Example of Data Frame Reception in Overrun Mode (i = 0, 1; j = 0 to 31)

(1) to (5) are the same as overwrite mode.

(6) In overrun mode, if the next message has been received before the NEWDATA bit is set to 0, the MSGLOST bit in the CiMCTLj register becomes 1 (message has been overrun) (j = 0 to 31). The new received message is discarded and a CANi error interrupt request is generated if the corresponding interrupt enable bit in the CiEIER register is 1 (interrupt enabled).

25.6.2   Transmission

Figure 25.45 shows an operation example of data frame transmission. This example shows an operation of transmitting messages that have been set in registers CiMCTL0 and CiMCTL1 (i = 0, 1).
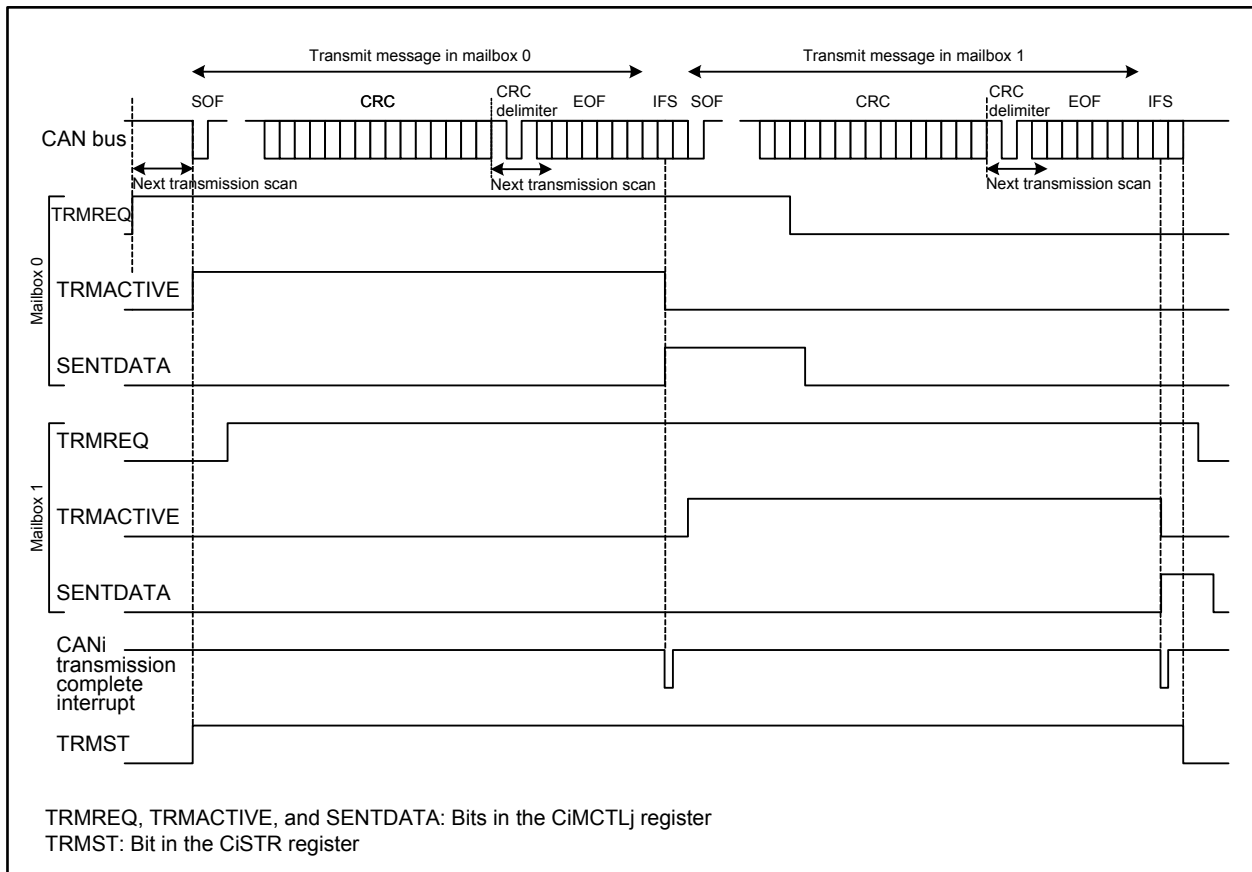

Figure 25.45 Operation Example of Data Frame Transmission (i = 0, 1; j = 0 to 31)

(1) When the TRMREQ bit in the CiMCTLj register is set to 1 (transmit mailbox) in the bus-idle state, the mailbox scan procedure starts to decide the highest-priority mailbox for transmission (j = 0 to 31). Once the transmit mailbox is decided, the TRMACTIVE bit in the CiMCTLj register becomes 1 (from when a transmission request is received until transmission is completed, or an error/ arbitration lost has occurred), the TRMST bit in the CiSTR register becomes 1 (transmission in progress), and the CAN module starts transmission. [1]

(2) If other TRMREQ bits are set, the transmission scan procedure starts with the CRC delimiter for the next transmission.

(3) If transmission is completed without losing arbitration, the SENTDATA bit in the CiMCTLj register becomes 1 (transmission completed) and the TRMACTIVE bit becomes 0 (transmission is pending, or no transmission request). If the interrupt enable bit in the CiMIER register is 1 (interrupt enabled), the CANi transmission complete interrupt request is generated.

(4) When requesting the next transmission from the same mailbox, set bits SENDTDATA and TRMREQ to 0, then set the TRMREQ bit to 1 after checking that bits SENDTDATA and TRMREQ have been set to 0.

Note:
1.   If arbitration is lost after the CAN module starts transmission, the TRMACTIVE bit becomes 0. The transmission scan procedure is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following the loss of arbitration, the transmission scan procedure is performed again from the start of the error delimiter to search for the highest-priority transmit mailbox.

25.7   CAN Interrupts

The CAN module provides the following CAN interrupts:
- CANi wakeup interrupt (i = 0, 1)
- CANi reception complete interrupt
- CANi transmission complete interrupt
- CANi receive FIFO interrupt
- CANi transmit FIFO interrupt
- CANi error interrupt

There are eight types of interrupt sources for the CANi error interrupts. These sources can be determined by checking the CiEIFR register.
- Bus error
- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery
- Receive overrun
- Overload frame transmission
- Bus lock

26. I/O Pins

Each pin of the MCU functions as a programmable I/O port or an I/O pin for integrated peripherals. These functions can be switched by the function select registers. The pull-up resistors are enabled for every group of four pins. However, when a pin functions as an output pin, a pull-up resistor is disabled regardless of the register settings.

Figure 26.1 shows a block diagram of typical I/O pin.
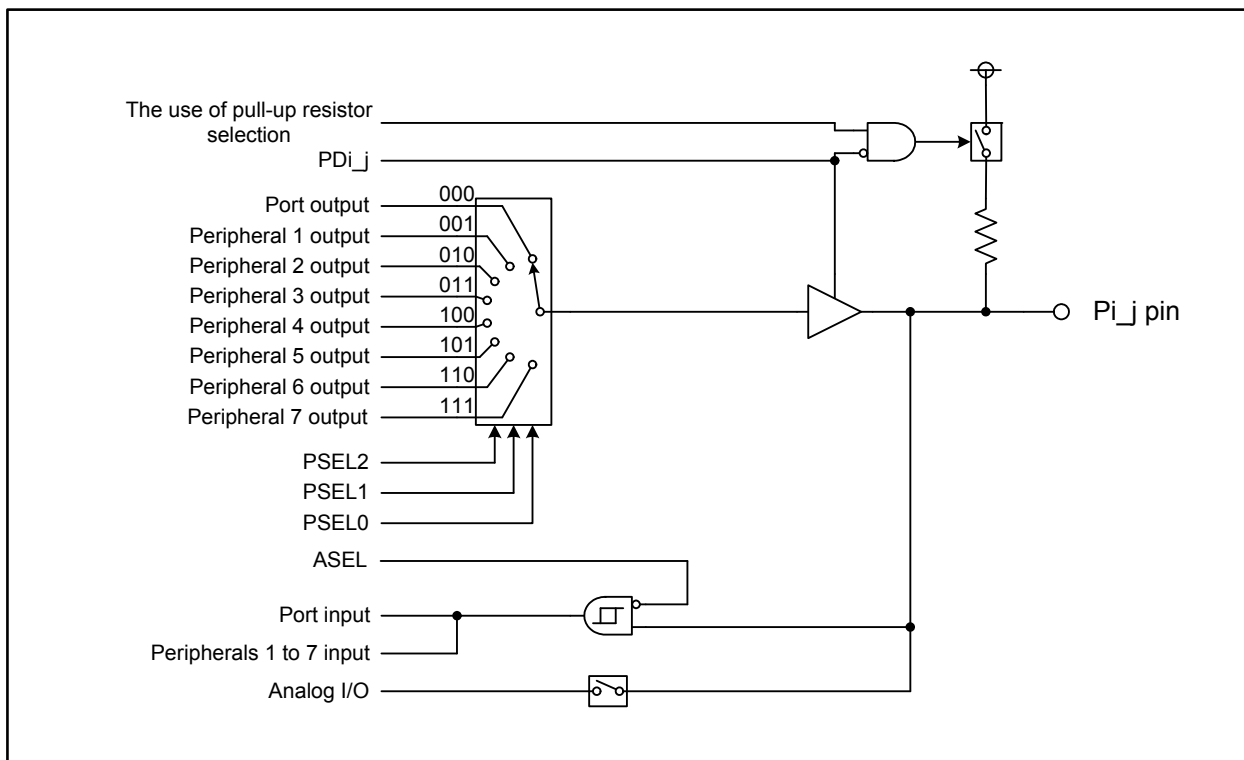

Figure 26.1   Typical I/O Pin Block Diagram (i = 0 to 15; j = 0 to 7)

The registers to control I/O pins are as follows: port Pi direction register (PDi register), output function select registers, and pull-up control registers. The PDi register selects the input or output state of pins. The output function select registers which select output function consist of bits PSEL2 to PSEL0, and ASEL. Bits PSEL2 to PSEL0 select a function as a programmable I/O or peripheral output (except analog output). The ASEL bit prevents the increase in power consumption of input buffer caused by an intermediate potential when a pin functions as an analog I/O pin. The pull-up control registers enable/disable the pull-up resistors. To use a pin as an analog I/O pin, set the PDi_j bit to 0 (input), bits PSEL2 to PSEL0 to 000b, and the ASEL bit to 1.

The input-only port P8_5 shares a pin with $\overline{\text{NMI}}$ and has neither function select register nor the corresponding direction bit. Port P14_1 also functions as an input-only port. The function select register and bit 1 in the PD14 register are reserved. Port P9 is protected from unexpected write accesses by the PRC2 bit in the PRCR register. Ports P3, P7, and P8 are protected from unexpected write accesses by the PRC30 bit in the PRCR3 register (refer to 9. "Protection").

26.1   Port Pi Direction Register (PDi Register, i = 0 to 15)

The PDi register selects the input or output state of pins. Bits in this register correspond to respective pins.

Figure 26.2 shows the PDi register.

No register bit is provided for port P8_5. For port P14_1, a reserved bit is provided.

The PD9 register is protected from unexpected write accesses by setting the PRC2 bit in the PRCR register. Registers PD3, PD7, and PD8 are protected by the PRC30 bit in the PRCR3 register (refer to 9. "Protection").

Port Pi Direction Register (i = 0 to 15)

	Symbol	Address	Reset Value
b7 b6 b5 b4 b3 b2 b1 b0	PD0 to PD3 [1]	03C2h, 03C3h, 03C6h, 03C7h	0000 0000b
	PD4 to PD7 [1]	03CAh, 03CBh, 03CEh, 03CFh	0000 0000b
	PD8 [1, 2]	03D2h	00X0 0000b
	PD9 [3], PD10	03D3h, 03D6h	0000 0000b
	PD11 [2]	03D7h	XXX0 0000b
	PD12, PD13	03DAh, 03DBh	0000 0000b
	PD14 [2, 4]	03DEh	X000 0X0Xb
	PD15	03DFh	0000 0000b

Bit Symbol	Bit Name	Function	RW
PDi_0	Port Pi_0 Direction Bit [2]	0: Input port 1: Output port	RW
PDi_1	Port Pi_1 Direction Bit [4]	0: Input port 1: Output port	RW
PDi_2	Port Pi_2 Direction Bit [2]	0: Input port 1: Output port	RW
PDi_3	Port Pi_3 Direction Bit	0: Input port 1: Output port	RW
PDi_4	Port Pi_4 Direction Bit	0: Input port 1: Output port	RW
PDi_5	Port Pi_5 Direction Bit [2]	0: Input port 1: Output port	RW
PDi_6	Port Pi_6 Direction Bit [2]	0: Input port 1: Output port	RW
PDi_7	Port Pi_7 Direction Bit [2]	0: Input port 1: Output port	RW

Notes:
1. Rewrite registers PD3, PD7, and PD8 after setting the PRC30 bit in the PRCR3 register to 1 (write enabled).
2. The PD8_5 bit in the PD8 register, bits PD11_5 to PD11_7 in the PD11 register, and bits PD14_0, PD14_2, and PD14_7 in the PD14 register are unavailable on this MCU. If necessary, set these bits to 0. The read value is undefined.
3. Set the PRC2 bit in the PRCR register to 1 (write enabled) just before rewriting the PD9 register. No interrupt handling or DMA transfers should be inserted between these two instructions.
4. The PD14_1 bit in the PD14 register is reserved. This bit should be written with 0.

Figure 26.2   Registers PD0 to PD15

26.2   Output Function Select Registers

When a programmable I/O port and peripheral output share a pin, these registers select the output function of the pin. Regardless of the register settings, signals are input to all the connected peripherals. An output function select register consists of bits PSEL2 to PSEL0, and ASEL. Bits PSEL2 to PSEL0 select a function as programmable I/O or peripheral output (except analog output). The ASEL bit prevents the increase in power consumption caused by an intermediate potential generated when a pin functions as an analog I/O pin.

Table 26.1 shows the peripherals assigned to each PSEL2 to PSEL0 bit combination, and Figures 26.3 to 26.18 show the function select registers.

Note that ports P8_5 and P14_1 (input only) have no output function select registers.

The P9_iS register is protected from unexpected write accesses by setting the PRC2 bit in the PRCR register and registers P3_iS, P7_iS, and P8_iS are protected by the PRC30 bit in the PRCR3 register (refer to 9. "Protection").

Table 26.1   Peripheral Assignment

2. Do not use this combination.

Figure 26.18 Registers P15_0S to P15_7S

Port P15_i shares a pin with the serial interface (UART3 and UART4), intelligent I/O group 0 (IIO0), and AN15_i input for the A/D converter (i = 0 to 7).

To use it as an output pin, set the PD15_i bit to 1 (port P15_i functions as an output port) and select a function according to Figure 26.18. To use it as an input pin (except for the A/D converter), set the PD15_i bit to 0 (port P15_i functions as an input port). To use it as an input pin for the A/D converter, set the P15_iS register to 80h and the PD15_i bit to 0.

26.3   Input Function Select Registers

When a peripheral input is assigned to multiple pins, these registers select which input pin should be connected to the peripheral.
Figures 26.19 to 26.24 show the input function select registers.

26.5   Port Control Register (PCR Register)

Figure 26.30 shows the PCR register.

This register selects an output mode for port P1 between push-pull output and pseudo-N-channel open drain output. When the PCR0 bit is set to 1, the P-channel transistor in the output buffer is turned off. Note that port P1 cannot be a perfect open drain output due to remaining parasitic diode. The absolute maximum rating of the input voltage is, therefore, -0.3 V to VCC + 0.3 V (refer to Figure 26.31).

— (b7-b1)	No register bits; should be written with 0 and read as undefined value		—

Note:

1. This function is designated not to make port P1 a full open drain, but to turn off the P-channel transistor in the CMOS output buffer. Therefore, the absolute maximum rating of the input voltage is -0.3 V to VCC + 0.3 V.

Figure 26.30 PCR Register
Figure 26.31 Port P1 Output Buffer Configuration

26.6   Configuring Unused Pins

Tables 26.2 and Figure 26.33 show examples of configuring unused pins on the board.

Table 26.2   Unused Pin Configuration in Single-chip Mode [1]

Pin Name	Setting
Ports P0 to P15 (excluding ports P8_5 and P14_1) [2]	Configure as input ports so that each pin is connected to VSS via its own resistor; [3] or configure as output ports to leave the pins open
P14_1	Connect the pin to VSS via a resistor [3]
$\overline{\text{XOUT}}$ [4]	Leave pin open
$\overline{\text{NMI}}$ (P8_5)	Connect the pin to VCC via a resistor [3]
AVCC	Connect the pin to VCC
AVSS, VREF	Connect the pin to VSS
NSD	Connect the pin to VCC via a resistor of 1 to 4.7 kΩ

Notes:
1. Unused pins should be wired within 2 cm of the MCU.
2. When configuring the pins as output ports to leave them open, note that ports as inputs remain unchanged from when the reset is released until the mode transition is completed. During this transition, the power supply current may increase due to an undefined voltage level of the pins. In addition, the direction register value may change due to noise or program runaway caused by the noise. To avoid these situations, reconfigure the direction register regularly by software, which may achieve higher program reliability.
3. Select a resistance value that is appropriate for the system. A range from 10 to 100 kΩ is recommended
4. This setting is applicable when an external clock is applied to the XIN pin.

Pull-up/pull-down resistors

The figure shows the equivalent circuit of an input pin.
The equivalent input resistors (R_P and R_N) are calculated using input power current (I_{IL} and I_{IH}).

Example: When VCC = 5.0 V, $I_{IH} = I_{IL} = 5$ μA,

$$R_P = R_N = \frac{5.0}{5 \times 10^{-6}} = 1 \text{ M}\Omega$$

Since the voltage (V_{IH}) defined as high is more than 0.7 VCC, the resistance value R should satisfy the following expression:

$$R//R_P : R_N = 0.3 : 0.7$$

That is,

$$R = \frac{3R_P R_N}{7R_P - 3R_N}$$

Specifically,
Example: When VCC = 5.0 V, $I_{IH} = I_{IL} = 5$ μA,

$$R = \frac{3 \times 10^6 \times 10^6}{7 \times 10^6 - 3 \times 10^6} = 750000$$

The maximum pull-up resistor R is approximately 750 kΩ.
The actual resistance value is the calculated value with some margins.

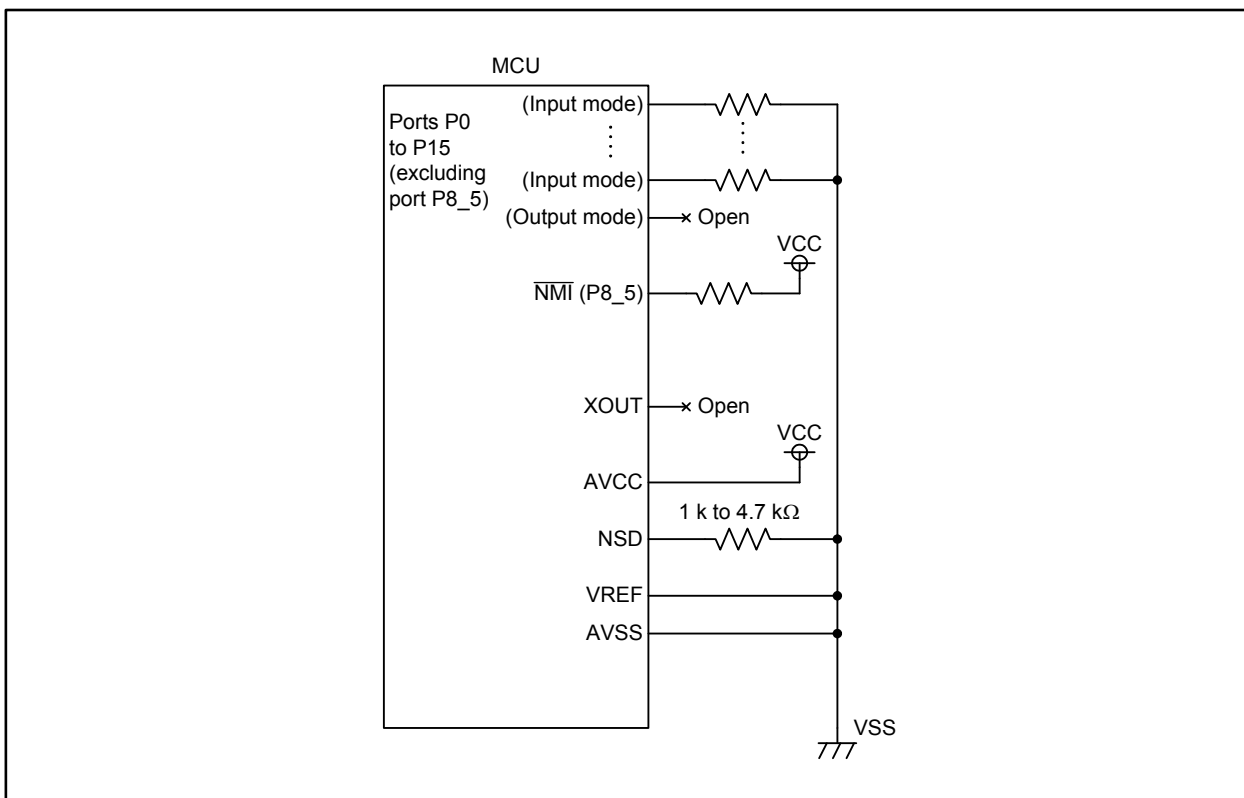

Figure 26.33 Unused Pin Configuration

27. Flash Memory

27.1   Overview

The flash memory can be programmed in the following three modes: CPU rewrite mode, standard serial I/O mode, and parallel I/O mode.
Table 27.1 lists specifications of the flash memory and Table 27.2 shows the overview of each rewrite mode.

Table 27.1   Flash Memory Specifications

Item	Specification
Rewrite modes	CPU rewrite mode, standard serial I/O mode, parallel I/O mode
Structure	Block architecture. Refer to Figure 27.1
Program operation	8-byte basis
Erase operation	1-block basis
Program and erase control method	Software commands
Protection types	Lock bit protect, ROM code protect, ID code protect
Software commands	9

Table 27.2   Flash Memory Rewrite Mode Overview

Rewrite Mode	CPU Rewrite Mode	Standard Serial I/O Mode	Parallel I/O Mode

Function	CPU executes a software command to rewrite the flash memory
	EW0 mode:
	  Rewritable in areas other than the on-chip flash memory
	EW1 mode:
	  Rewritable in areas other than specified blocks to be rewritten
		A dedicated serial programmer rewrites the flash memory
		Standard serial I/O mode 1:
		  Synchronous serial I/O selected
		Standard serial I/O mode 2:
		  UART selected
			A dedicated parallel programmer rewrites the flash memory

CPU operating mode	Single-chip mode	Standard serial I/O mode	Parallel I/O mode
Programmer	—	Serial programmer	Parallel programmer
On-board programming	Supported	Supported	Not supported

Figure 27.1 shows the on-chip flash memory structure.
The on-chip flash memory contains program area to store user programs, and data area/data flash to store the result of user programs. The program area consists of blocks 0 to 9, and data area/data flash consists of blocks A and B.
Each block can be individually protected (locked) from programming or erasing by setting the lock bit.
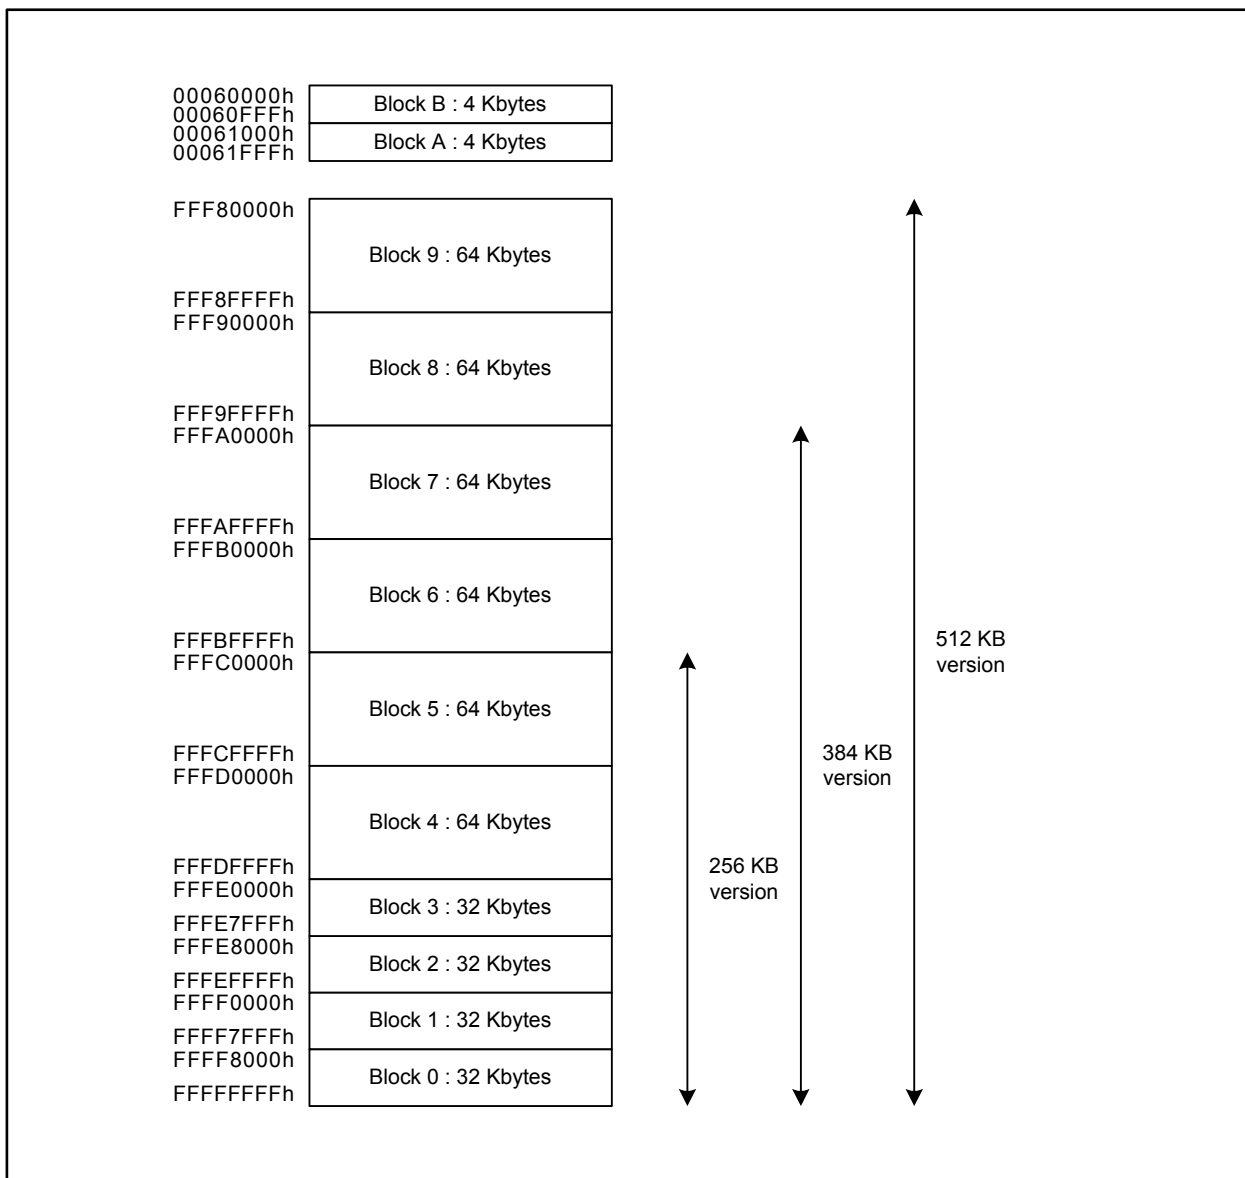

Figure 27.1   On-chip Flash Memory Block Diagram

27.2   Flash Memory Protection

There are three types of protection as shown in Table 27.3. Lock bit protection is intended to prevent accidental write or erase by program runaway. ROM code protection and ID code protection are intended to prevent read or write by a third party.

Table 27.3   Protection Types and Characteristics

Protection Type	Lock Bit Protection	ROM Code Protection	ID Code Protection
Protected operations	Erase, write	Read, write	Read, erase, write
Protection available in	CPU rewrite mode Standard serial I/O mode Parallel I/O mode	Parallel I/O mode	Standard serial I/O mode
Protection available for	Individual blocks	Entire flash memory	Entire flash memory
Protection settings	Setting 0 to the lock bit of block to be protected	Setting the protect bit of any block to 0	Writing the program which has set an ID code to specified address
Protection disabled by	Setting the LBD bit in the FMR register to 1 (lock bit protection disabled), or by erasing the blocks whose lock bits are set to 0 to permanently disable the protection	Erasing all blocks whose protect bits are set to 0	Sending a proper ID code from the serial programmer

27.2.1   Lock Bit Protection

This protection can be used in all three rewrite modes. When the lock bit protection is enabled, all blocks whose lock bits are set to 0 (locked) are protected against programming and erasing.
To set the lock bit to 0, the lock bit program command must be issued.
To temporarily disable the protection of all protected blocks, disable the lock bit protection itself by setting the LBD bit in the FMR1 register to 1 (lock bit protection disabled). The protection of a protected block is disabled permanently and its lock bit becomes 1 (unlocked) if the block is erased.

27.2.2   ROM Code Protection

This protection can only be used in parallel I/O mode. When the ROM code protection is enabled, the entire flash memory is protected against reading and writing.
To disable the protection, erase all the blocks whose protect bits are set to 0 (protected).
Each block has two protect bits. Setting any protect bit to 0 by a software command enables the protection for the entire flash memory. Table 27.4 lists protect bit addresses.

Table 27.4   Protect Bit Addresses

Block	Protect Bit 0	Protect Bit 1
Block B	00060100h	00060300h
Block A	00061100h	00061300h
Block 9	FFF80100h	FFF80300h
Block 8	FFF90100h	FFF90300h
Block 7	FFFA0100h	FFFA0300h
Block 6	FFFB0100h	FFFB0300h
Block 5	FFFC0100h	FFFC0300h
Block 4	FFFD0100h	FFFD0300h
Block 3	FFFE0100h	FFFE0300h
Block 2	FFFE8100h	FFFE8300h
Block 1	FFFF0100h	FFFF0300h
Block 0	FFFF8100h	FFFF8300h

27.2.3   ID Code Protection

This protection can only be used in standard serial I/O mode. A command from the serial programmer is to be accepted when the 7-byte ID code sent from the serial programmer matches the ID code programmed in the flash memory. However, when the reset vector is FFFFFFFFh, the ID code check is skipped because the flash memory is considered to be blank. When the reset vector is FFFFFFFFh and the ROM code protection is enabled, only the block erase command is accepted.

The ID codes sent from the serial programmer are consecutively numbered as ID1, ID2, ..., and ID7. ID codes programmed in the flash memory, also numbered as ID1, ID2, ..., and ID7, are assigned to addresses FFFFFFE8h, FFFFFFE9h, ..., and FFFFFFEEh as shown in Figure 27.2. The ID code protection is enabled when a program which has an ID code set in the corresponding address is written to the flash memory.

FFFFFFDFh to FFFFFFDCh	Undefined instruction vector		
FFFFFFE3h to FFFFFFE0h	Overflow interrupt vector		
FFFFFFE7h to FFFFFFE4h	BRK instruction interrupt vector		
FFFFFFEBh to FFFFFFE8h	ID4	ID3	ID2	ID1
FFFFFFEFh to FFFFFFECh	OFS [1]	ID7	ID6	ID5
FFFFFFF3h to FFFFFFF0h	Watchdog timer interrupt vector		
FFFFFFF7h to FFFFFFF4h	Reserved		
FFFFFFFBh to FFFFFFF8h	NMI interrupt vector		
FFFFFFFFh to FFFFFFFCh	Reset vector		

4 bytes

Note:
1. Refer to the Watchdog Timer chapter for the OFS area.

Figure 27.2   Addresses for ID Code Stored

27.3   CPU Rewrite Mode

In CPU rewrite mode, the CPU executes software commands to rewrite the flash memory. The CPU accesses the flash memory not via the CPU buses, but via the dedicated flash memory rewrite buses (refer to Figure 27.3).
Figure 27.3   Flash Memory Access Path in CPU Rewrite Mode

Bus setting for flash memory rewrite should be performed by the FEBC register. Refer to 27.3.1 "Flash Memory Rewrite Bus Timing" and 29. "Electrical Characteristics" for the appropriate bus setting.

The CPU rewrite mode contains modes EW0 and EW1 as shown in Table 27.5.

Table 27.5   EW0 and EW1 Modes

Item	EW0 Mode	EW1 Mode
Rewrite program executable spaces	Spaces other than the on-chip flash memory	Internal spaces other than specified blocks to be rewritten, internal RAM
Restrictions on software commands	None	• Do not execute either the program command or the block erase command for blocks where the rewrite control programs are written to • Do not execute the enter read status register mode command • Execute the enter read lock bit status mode command in RAM • Execute the enter read protect bit status mode command in RAM
Mode after program/ erase operation	Read status register mode	Read array mode
CPU state during program/erase operation	Operating	In a hold state (I/O ports maintain the state before the command was executed)
Flash memory state detection by	• Reading the FMSR0 register by a program • Executing the enter read status register mode command to read data	• Reading the FMSR0 register by a program
Other restrictions	None	• The watchdog timer is disabled in count source protect mode • Disable interrupts (except NMI) and DMA transfer during program/erase operation

To select CPU rewrite mode, the FEW bit in the FMCR register should be set to 1. Then, EW0 mode/EW1 mode can be selected by setting the EWM bit in the FMR0 register.
Registers FMCR and FMR0 are protected by registers PRR and FPR0, respectively.
Figures 27.4 to 27.11 show associated registers.

Figure 27.11 FBPM1 Register

27.3.1   Flash Memory Rewrite Bus Timing

The bus setting for the flash memory rewrite is performed by setting the FEBC register. This section specifically describes the setting of the FEBC register.

The reference clock is the base clock set with bits BCD1 and BCD0 in the CCR register. Time duration including tsu, tw, tc, and th are specified by the number of base clock cycles.

Tables 27.6 to 27.8 show the correlation of the read cycle and setting of bits MPY1, MPY0, and FWR4 to FWR0, according to peripheral bus clock divide ratios. Tables 27.9 to 27.11 show the correlation of the write cycle and setting of bits MPY1, MPY0, FSUW1, FSUW0, FWW1, and FWW0. Associated read/write timings are illustrated in Figures 27.12 and 27.13, respectively.

Read/write cycle timing is selected from the tables below to meet the timing requirements in the CPU rewrite mode described in the electrical characteristics.
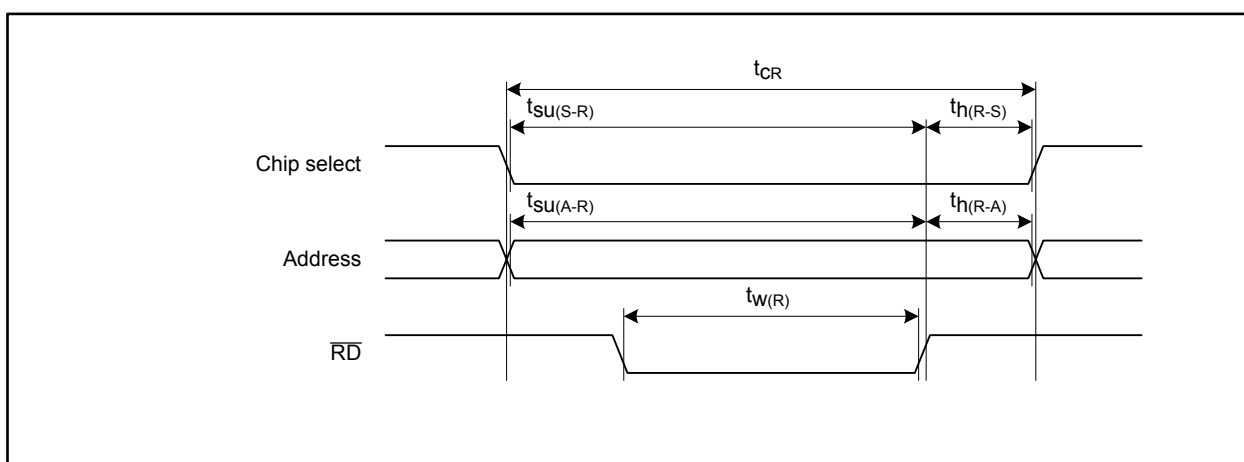

Figure 27.12 Read Timing

27.3.2   Software Commands

In CPU rewrite mode, software commands enable program and erase operations for the flash memory.
Writing commands and reading/writing data should be performed in 16-bit units.
Table 27.12 lists the software commands.

Table 27.12   Software Commands

Command	First Command Cycle		Second Command Cycle	
	Address	Data	Address	Data
Enter read array mode	FFFFF800h	00FFh	—	—
Enter read status register mode [1]	FFFFF800h	0070h	—	—
Clear status register	FFFFF800h	0050h	—	—
Program [2]	FFFFF800h	0043h	WA	WD
Block erase	FFFFF800h	0020h	BA	00D0h
Lock bit program	FFFFF800h	0077h	BA	00D0h
Read lock bit status	FFFFF800h	0071h	BA	00D0h
Enter read lock bit status mode [3]	FFFFF800h	0071h	—	—
Protect bit program	FFFFF800h	0067h	PBA	00D0h
Enter read protect bit status mode [3]	FFFFF800h	0061h	—	—

WA: Even address to be written
WD: 16-bit data to be written
BA: Even address within a specific block
PBA: Protect bit address (refer to Table 27.4)

Notes:
1. This command cannot be executed in EW1 mode.
2. The program is performed in 64-bit (4-word) units. A sequence of commands consists of commands from the second to fifth. The upper 29 bits of the address WA should be fixed and the lower 3 bits of respective commands from the second to fifth should be set to 000b, 010b, 100b, and 110b for the addresses 0h, 2h, 4h, and 6h, or 8h, Ah, Ch, and Eh.
3. This command should be executed in RAM.

27.3.3   Mode Transition

CPU rewrite mode supports four flash memory operating modes:
- Read array mode
- Read status register mode
- Read lock bit status mode
- Read protect bit status mode

When reading the flash memory in these modes, the memory data, the status register value, the state of the lock bit in the read block, and the state of the protect bit are individually read. Details are listed in Tables 27.13 to 27.15.

Table 27.13   Status Register

Bit	Bit Symbol	Bit Name	Definition	
			0	1
b15-b8	—	Disabled bit	—	—
b7	SR7	Sequencer status	BUSY	READY
b6	—	Reserved bit	—	—
b5	SR5	Erase status	Successfully completed	Error
b4	SR4	Program status	Successfully completed	Error
b3	—	Reserved bit	—	—
b2	—	Reserved bit	—	—
b1	—	Reserved bit	—	—
b0	—	Reserved bit	—	—

Table 27.14   Lock Bit Status

Bit	Bit Symbol	Bit Name	Definition	
			0	1
b15-b7	—	Disabled bit	—	—
b6	LBS	Lock bit status	Locked	Unlocked
b5-b0	—	Disabled bit	—	—

Table 27.15   Protect Bit Status

Bit	Bit Symbol	Bit Name	Definition	
			0	1
b15-b7	—	Disabled bit	—	—
b6	PBS	Protect bit status	Protected	Unprotected
b5-b0	—	Disabled bit	—	—

In these operating modes, program or erase operation can be performed by software commands. After an operation is completed, the flash memory module automatically enters read array mode (in EW1 mode) or read status register mode (in EW0 mode).

27.3.4   Issuing Software Commands

This section describes how to issue software commands.
These commands should be issued while the RDY bit in the FMSR0 register is 1 (ready).

27.3.4.1   Enter Read Array Mode Command

Execute this command to enter read array mode.
When 00FFh is written to address FFFFF800h, the flash memory enters read array mode. In this mode, the value stored to a given address in memory can be read.
In EW1 mode, the flash memory is always in read array mode.

27.3.4.2   Enter Read Status Register Mode

Execute this command to enter read status register mode.
When 0070h is written to address FFFFF800h, the status register value is read in any address of the flash memory.
Do not issue this command in EW1 mode.

27.3.4.3   Clear Status Register

Execute this command to reset the status register in the flash memory.
When 0050h is written to address FFFFF800h, bits SR5 and SR4 in the status register become 0 (successfully completed) (refer to Table 27.13). Consequently, bits EERR and WERR in the FMSR0 register become 0 (no errors).

27.3.4.4   Program Command

Execute this command to program the flash memory in 8-byte (4-word) units.

To start automatic programming (program and program-verify operations), write 0043h to address FFFFF800h, then write data to addresses 8n + 0 to 8n + 6. Verify that the FCA bit in the FMR0 register is 0 just before executing the final command.

To monitor the automatic program operation, read the RDY bit in the FMSR0 register. This bit becomes 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.

The operation result can be verified by the WERR bit in the FMSR0 register (refer to 27.3.5 "Status Check").

Do not write additional data to an address that is already programmed.
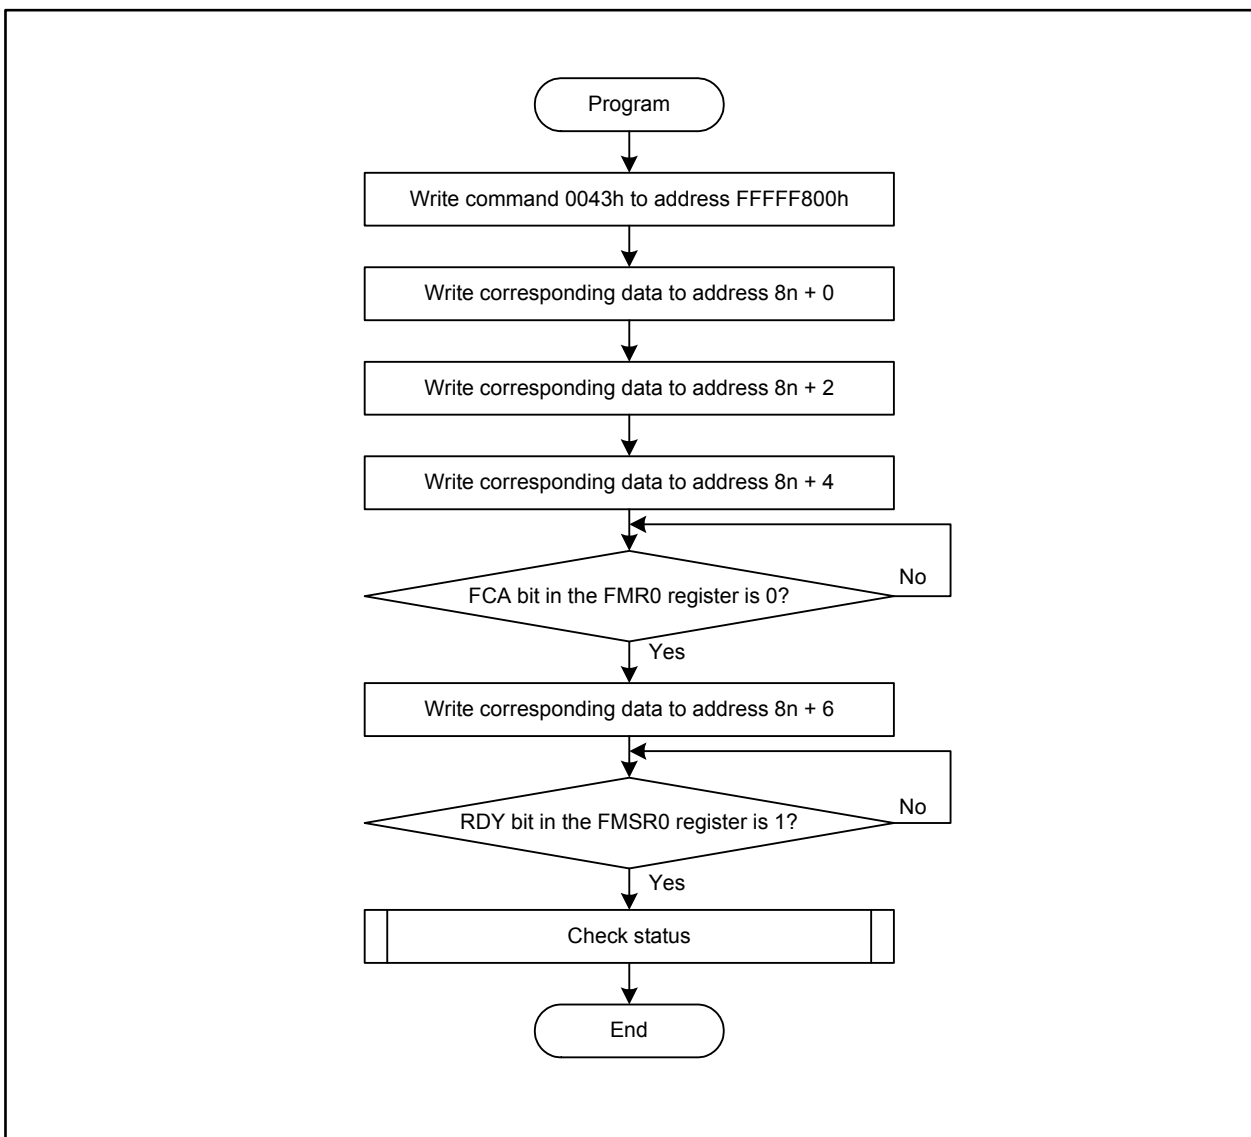

Figure 27.14 Program Command Execution Flowchart

27.3.4.5   Block Erase Command

Execute this command to erase a specified block in the flash memory.

To start automatic erasing of a specified block (erase and erase-verify operations), write 0020h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, then write 00D0h to an even address in the corresponding block.

To monitor the automatic erase operation, read the RDY bit in the FMSR0 register. This bit becomes 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.

The operation result can be verified by the EERR bit in the FMSR0 register (refer to 27.3.5 "Status Check").
Figure 27.15 Block Erase Command Execution Flowchart

27.3.4.6   Lock Bit Program Command

Execute this command to lock a specified block in the flash memory.

To lock the block, write 0077h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, then write 00D0h to an even address in the corresponding block. Then the lock bit of the block becomes 0 (locked).

To monitor the lock bit program, read the RDY bit in the FMSR0 register. This bit becomes 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.

The state of the lock bit can be verified by the read lock bit status command if the LBM bit in the FMR0 register is 1 (read by the LBS bit) (refer to 27.3.4.7 "Read Lock Bit Status Command"). If the LBM bit is 0 (read via data bus), enter read lock bit status mode (refer to 27.3.4.8 "Enter Read Lock Bit Status Mode Command").
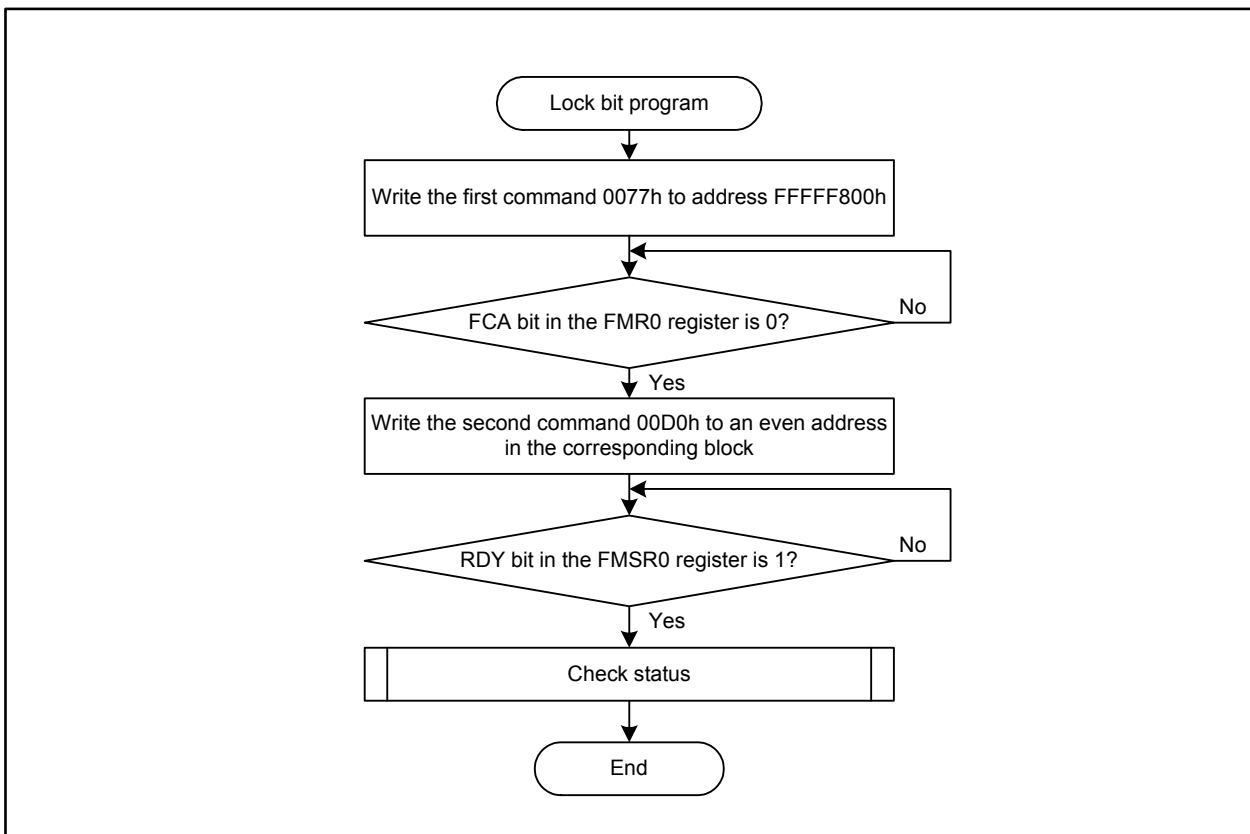

Figure 27.16 Lock Bit Program Command Execution Flowchart

27.3.4.7   Read Lock Bit Status Command

Execute this command to verify if a specified block in the flash memory is locked. This command can be used when the LBM bit in the FMR0 register is 1 (read by the LBS bit).

The LBS bit in the FMSR0 register reflects the lock bit status of the specified block when the following is performed: first write 0071h to address FFFFF800h and verify that the FCA bit in the FMR0 register becomes 0. Then write 00D0h to an even address of the corresponding block.

Read the LBS bit after the RDY bit in the FMSR0 register becomes 1 (ready).
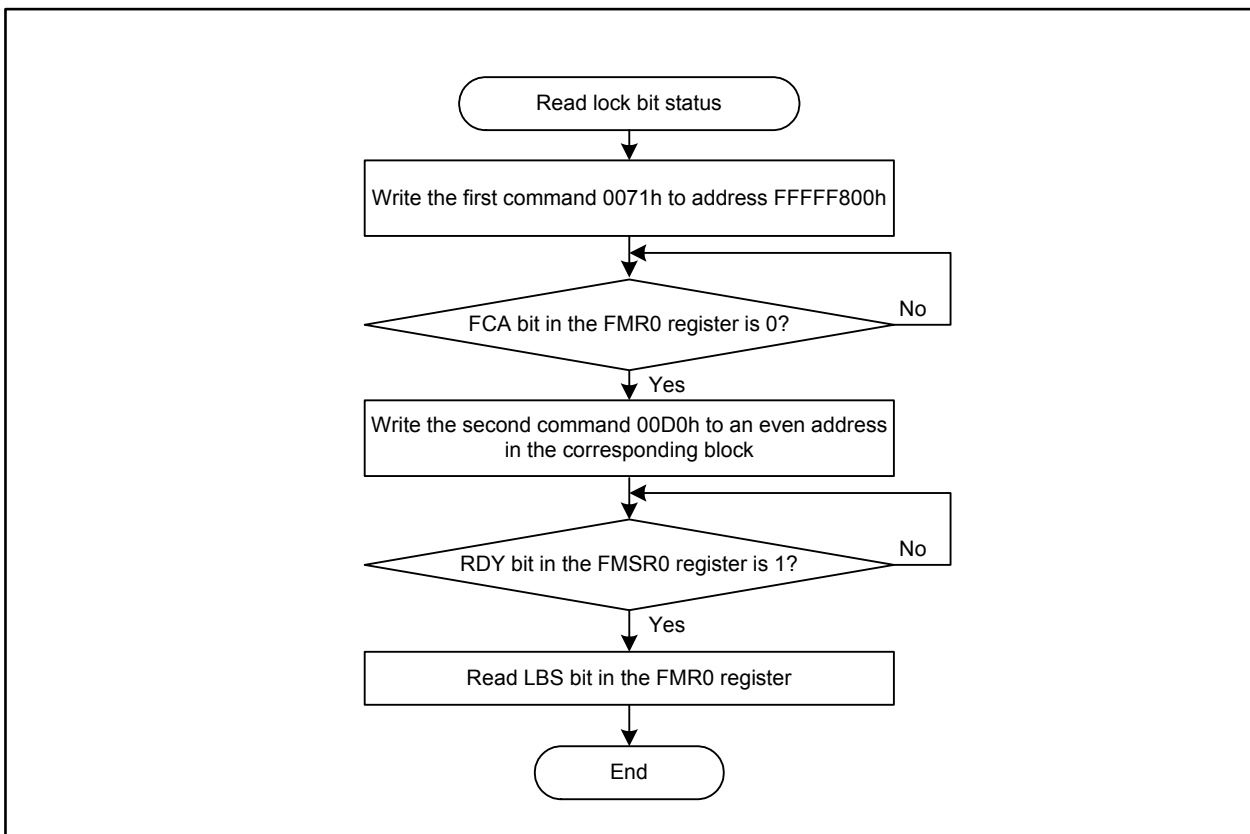

Figure 27.17 Read Lock Bit Status Command Execution Flowchart

27.3.4.8   Enter Read Lock Bit Status Mode Command

Execute this command to enter read lock bit status mode. This command is enabled when the LBM bit in the FMR0 register is 0 (read via data bus).

To read the lock bit status of the read block, write 0071h to address FFFFF800h (refer to Table 27.14). The status is read in any address of the flash memory.

Execute this command in RAM.

27.3.4.9   Protect Bit Program Command

Execute this command to protect a specific block in the flash memory. ROM code protection is enabled by setting one of the protect bits of the block to 0.

To set the protect bit of the designated block to 0 (protected), write 0067h to address FFFFF800h, verify that the FCA bit in the FMR0 register is 0, and then write 00D0h to the protect bit of the corresponding block (refer to Table 27.4).

To monitor the protect bit program, read the RDY bit in the FMSR0 register. This bit becomes 0 (busy) when the operation is in progress and 1 (ready) when the operation is completed.

To verify the state of protect bit, enter read protect bit status mode (refer to 27.3.4.10 "Enter Read Protect Bit Status Mode Command"), then read the flash memory.
Figure 27.18 Protect Bit Program Command Execution Flowchart

27.3.4.10   Enter Read Protect Bit Status Mode Command

Execute this command to enter read protect bit status mode.

To read the protect bit status of the read block, write 0061h to address FFFFF800h (refer to Table 27.15). The status is read from any address in the flash memory.

Execute this command in RAM.

27.3.5   Status Check

To verify if a software command is successfully executed, read the EERR or WERR bit in the FMSR0 register, or the SR5 bit or SR4 bit in the status register.
Table 27.16 lists status and errors indicated by these bits and Figure 27.19 shows the flowchart of the status check.

Table 27.16   Status and Errors

FMSR0 Register (Status Register)		Error	Source of Error
EERR bit (SR5 bit)	WERR bit (SR4 bit)		
1	1	Command sequence error	• Data other than 00D0h or 00FFh (command to cancel) was written as the last command of two commands • An unavailable address was specified by an address specifying command
1	0	Erase error	• Attempted to erase a locked block • Corresponding block was not erased properly
0	1	Program error	• Attempted to program a locked block • Data was not programmed properly • Lock bit was not programmed properly • Protect bit was not programmed properly
0	0	No error	
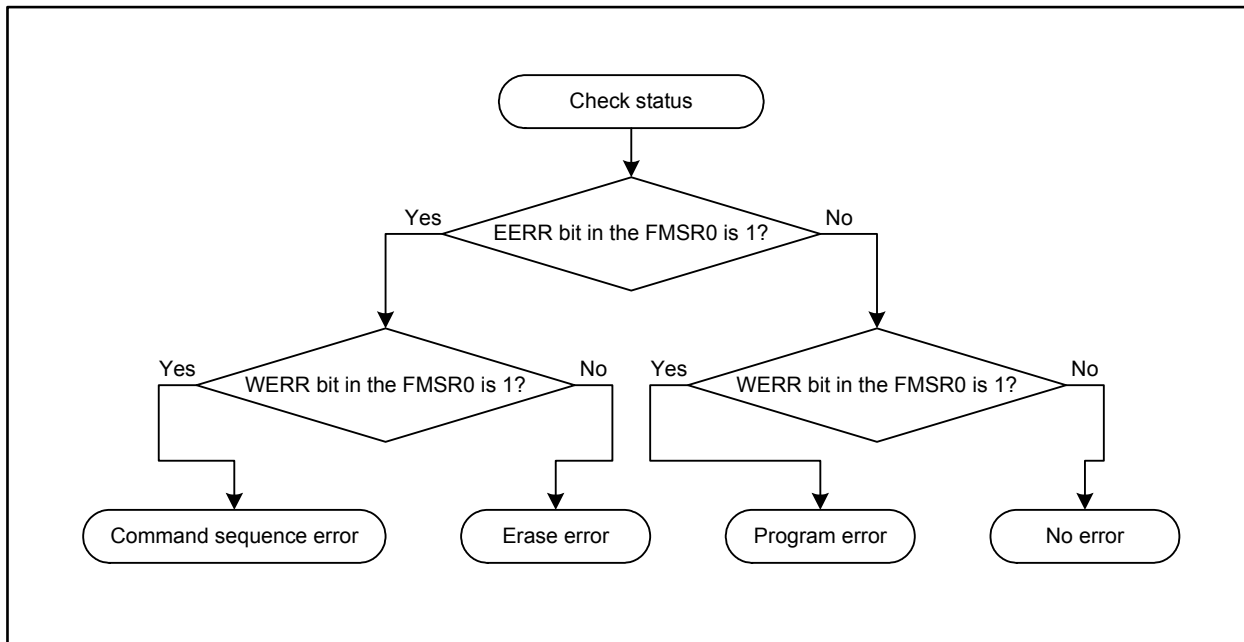

Figure 27.19 Status Check Flowchart

When an error occurs, execute the clear status register command and then handle the error.
If erase errors or program errors occur frequently even though the program is correct, the corresponding block may be disabled.

27.4   Standard Serial I/O Mode

In standard serial I/O mode, an R32C/156 Group compatible serial programmer can be used to rewrite the flash memory while the MCU is mounted on a board.

For further information on the serial programmer, contact your serial programmer manufacturer and refer to the user's manual included with the serial programmer for instructions.

As shown in Table 27.17, this mode provides two types of transmit/receive mode: Standard serial I/O mode 1 which uses a synchronous serial interface, and standard serial I/O mode 2 which uses UART.

Table 27.17   Standard Serial I/O Mode Specifications

Item		Standard Serial I/O Mode 1	Standard Serial I/O Mode 2
Transmit/receive mode		Synchronous serial I/O	UART
Transmit/receive bit rate		High	Low
Serial interface to be used		UART1	UART1
Pin settings	CNVSS	High	High
	$\overline{\text{CE}}$ (P5_0)	High	High
	$\overline{\text{EPM}}$ (P5_5)	Low	Low
Pin functions	SCLK (P6_5)	In reset: Low In transmission/reception: Transmit/receive clock	In reset: Low In transmission/reception: Unused
	BUSY (P6_4)	BUSY signal	Monitor to check program operation
	RXD (P6_6)	Serial data input	Serial data input
	TXD (P6_7)	Serial data output	Serial data output

Table 27.18 lists the pin definitions and functions in standard serial I/O mode. Figures 27.20 and 27.21 show examples of a circuit application in standard serial I/O modes 1 and 2, respectively. Refer to the serial programmer user manual to handle pins controlled by the serial programmer.

Table 27.18   Pin Definitions and Functions in Standard Serial I/O Mode

Pin Name	Function	I/O	Description
VCC, VSS	Power supply input	I	Applicable as follows: VCC = guaranteed voltage for program/erase operations, VSS = 0 V
VDC1, VDC0	Connecting pins for decoupling capacitor	—	A decoupling capacitor for internal voltage should be connected between VDC0 and VDC1
CNVSS	CNVSS	I	This pin should be connected to VCC via a resistor
$\overline{RESET}$	Reset input	I	Reset input pin. While the $\overline{RESET}$ pin is driven low, at least 20 clock cycles should be input at the XIN pin
XIN	Main clock input	I	A ceramic resonator or a crystal oscillator should be connected between pins XIN and XOUT. An external clock should be input at XIN while leaving XOUT open
XOUT	Main clock output	O	
NSD	Debug port	I/O	This pin should be connected to VCC via a resistor of 1 to 4.7 kΩ
AVCC, AVSS	Analog power supply	I	AVCC and AVSS should be connected to VCC and VSS, respectively
VREF	Reference voltage input	I	Reference voltage input for the A/D converter and D/A converter
P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7	Input port	I	High or low should be input, or the ports should be left open
P5_0	$\overline{CE}$ input	I	High should be input
P5_1 to P5_4	Input port	I	High or low should be input, or the ports should be left open
P5_5	$\overline{EPM}$ input	I	Low should be input
P5_6, P5_7, P6_0 to P6_3	Input port	I	High or low should be input, or the ports should be left open
P6_4	BUSY output	O	Standard serial I/O mode 1: BUSY output pin Standard serial I/O mode 2: Program operation monitor
P6_5	SCLK input	I	Standard serial I/O mode 1: Serial clock input pin Standard serial I/O mode 2: Low should be input
P6_6	Data input RXD	I	Serial data input pin
P6_7	Data output TXD	O	Serial data output pin
P7_0 to P7_7, P8_0 to P8_4	Input port	I	High or low should be input, or the ports should be left open
P8_5	$\overline{NMI}$ input	I	This pin should be connected to VCC via a resistor
P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7	Input port	I	High or low should be input, or the ports should be left open
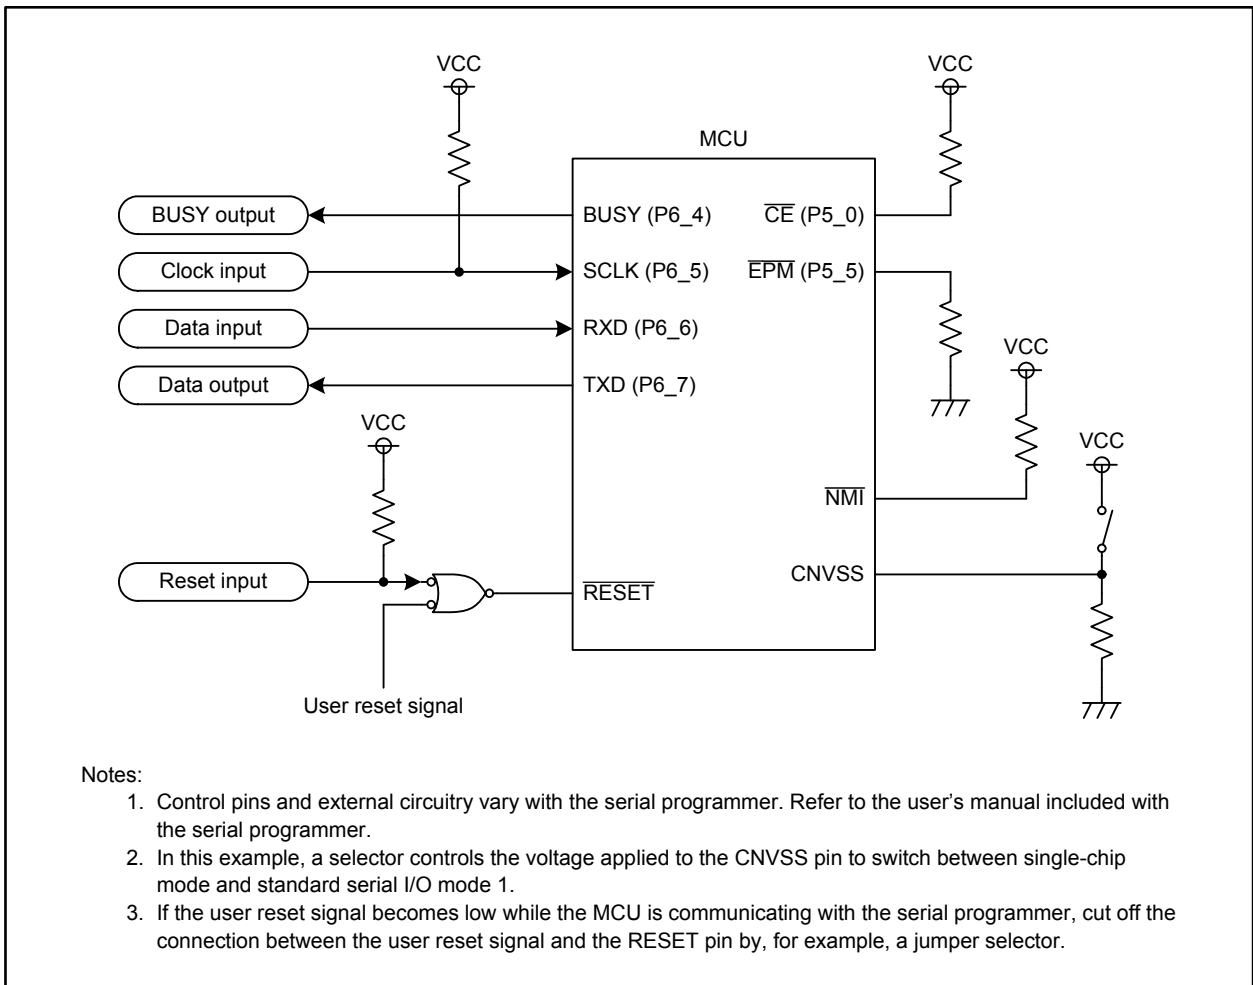

Figure 27.20 Circuit Application in Standard Serial I/O Mode 1

Notes:
1. Control pins and external circuitry vary with the serial programmer. Refer to the user's manual included with the serial programmer.
2. In this example, a selector controls the voltage applied to the CNVSS pin to switch between single-chip mode and standard serial I/O mode 1.
3. If the user reset signal becomes low while the MCU is communicating with the serial programmer, cut off the connection between the user reset signal and the RESET pin by, for example, a jumper selector.

Figure 27.21 Circuit Application in Standard Serial I/O Mode 2

27.5   Parallel I/O mode

In parallel I/O mode, an R32C/156 Group compatible parallel programmer can be used to rewrite the flash memory.

For further information on the parallel programmer, contact your parallel programmer manufacturer and refer to the user's manual included with your parallel programmer for instructions.

27.6 Notes on Flash Memory Rewriting

27.6.1 Note on Power Supply

- Keep the supply voltage constant within the range specified in the electrical characteristics while a rewrite operation on the flash memory is in progress. If the supply voltage goes beyond the guaranteed value, the device cannot be guaranteed.

27.6.2 Note on Hardware Reset

- Do not perform a hardware reset while a rewrite operation on the flash memory is in progress.

27.6.3 Note on Flash Memory Protection

- If an ID code written in an assigned address has an error, any read/write operation on the flash memory in standard serial I/O mode is disabled.

27.6.4 Notes on Programming

- Do not set the FEW bit in the FMCR register to 1 (CPU rewrite mode) in low speed mode or low power mode.
- When the EWM bit in the E2FM register is 1 (program or erase enabled), do not set the FEW bit in the FMCR register to 1.
- The program, block erase, lock bit program, and protect bit program are interrupted by an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt. If any of the software commands above are interrupted, erase the corresponding block and then execute the same command again. If the block erase command is interrupted, the lock bit and protect bit values become undefined. Therefore, disable the lock bit, and then execute the block erase command again.

27.6.5 Notes on Interrupts

- EW0 mode
  - To use interrupts assigned to the relocatable vector table, the vector table should be addressed in RAM space.
  - When an NMI, watchdog timer interrupt, oscillator stop detection interrupt, or low voltage detection interrupt occurs, the flash memory module automatically enters read array mode. Therefore, these interrupts are enabled even during a rewrite operation. However, the rewrite operation in progress is aborted by the interrupts and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.
  - Instructions BRK, INTO, and UND, which refer to data on the flash memory, cannot be used in this mode.

- EW1 mode
  - Interrupts assigned to the relocatable vector table should not be accepted during program or block erase operation.
  - The watchdog timer should not be used in count source protect mode. The watchdog timer interrupt should not be generated.
  - When an NMI, watchdog timer interrupt, oscillator stop detection interrupt, or low voltage detection interrupt occurs, the flash memory module automatically enters read array mode. Therefore, these interrupts are enabled even during a rewrite operation. However, the rewrite operation in progress is aborted by the interrupts and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the EWM bit in the FMR0 register to 1 (EW1 mode) and the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.

27.6.6   Notes on Rewrite Control Program

• EW0 mode
  • If the supply voltage drops during the rewrite operation of blocks having the rewrite control program, the rewrite control program may not be successfully rewritten, and the rewrite operation itself may not be performed. In this case, perform the rewrite operation by serial programmer or parallel programmer.

• EW1 mode
  • Do not rewrite blocks having the rewrite control program.

27.6.7   Notes on Number of Program/Erase Cycles and Software Command Execution Time

• The time to execute software commands (program, block erase, lock bit program, and protect bit program) increases as the number of program/erase cycles increases. If the number of program/ erase cycles exceeds the endurance value specified in the electrical characteristics, it may take an unpredictable amount of time to execute the software commands. The wait time for executing software commands should be set much longer than the execution time specified in the electrical characteristics.

27.6.8   Other Notes

• The minimum values of program/erase cycles specified in the electrical characteristics are the maximum values that can guarantee the initial performance of the flash memory. The program/ erase operation may still be performed even if the number of program/erase cycles exceeds the guaranteed values.
• Chips repeatedly programmed and erased for debugging should not be used for commercial products.

28. E^{2}PROM Emulation Data Flash

28.1 Overview

E^{2}PROM emulation data flash (hereafter referred to as E^{2}dataFlash) is an on-chip data flash which has features of serial E^{2}PROMs. It is erasable in much smaller blocks than the other data flash and can be programmed and erased without keeping the CPU away from its operation.

Table 28.1 lists the specifications and Figure 28.1 shows the block diagram of the E^{2}dataFlash.

Table 28.1   E^{2}dataFlash Specifications

Item	Specification	
	ECC disabled	ECC enabled
Memory size	4 Kbytes	2 Kbytes
Block size	32 bytes	16 bytes
Number of blocks	128	
Unit to be programmed	2 bytes	1 byte
Unit to be erased	1 block	
Program and erase control method	By software commands	
Software commands	4	
Error correction	None	1-bit error correctable

Figure 28.1   E^{2}dataFlash Block Diagram

The CPU indirectly accesses the E^{2}dataFlash via registers E2FA, E2FI, and E2FD which are set for SFR space.

Figures 28.2 to 28.8 show E^{2}dataFlash associated registers.

E²dataFlash Mode Register [(1)]

b7	b6	b5	b4	b3	b2	b1	b0
	0	0	0	0			

Symbol : E2FM
Address : 44FF0h
Reset Value : 0000 0000b

Bit Symbol	Bit Name	Function	RW
OM	Operating Mode Select Bit	0: Sleep mode 1: Normal operating mode	RW
RST	Reset Bit	0: Normal operating mode or sleep mode [(2)] 1: Reset [(3)]	RW
EWM	EW Mode Setting Bit [(4)]	0: Disable program/erase [(5)] 1: Enable program/erase	RW
— (b6-b3)	Reserved	Should be written with 0	RW
ECC	ECC Control Bit	0: ECC disabled 1: ECC enabled	RW

Notes:
1. Set the PRC41 bit in the PRCR4 register to 1 (write enabled) before rewriting this register.
2. Once this bit is set to 1, it should be set to 0 after the RDY bit in the E2FS0 register becomes 1 (ready).
3. When this bit is set to 1, the module stops ongoing operations to enter its initial state. However, the registers are not initialized.
4. When the MRS bit in the VRCR register is 1 (main regulator stopped), or when the FEW bit in the FMCR register is 1 (CPU rewrite mode), this bit should not be set to 1.
5. In this mode, any write access results in the E2FI register being set to 00F3h (read commands).

		E2FA	44FE3h-44FE0h	XXXX 0000h

Function	Setting Range	RW
Set an address to be accessed. The two upper bytes are read as undefined value	00062000h to 00062FFEh (when ECC disabled) 00062000h to 000627FFh (when ECC enabled)	RW

Figure 28.6   E2FA Register

E²dataFlash Instruction Register [1]

b15 b8 b7 b0		

Symbol	Address	Reset Value
E2FI	44FE9h-44FE8h	XX00h

Function	Setting Range	RW
Set an instruction for the flash memory. The upper byte is read as undefined value	0020h, 0040h, 0050h, 00D0h, 00F3h [2]	RW

Notes:
1. A 16-bit write/read access to this register should be performed.
2. Refer to the table below for details.

Setting Value	Instructions
0020h	Block Erase
0040h	Program
0050h	Clear Status Register
00D0h	Block Erase Confirm
00F3h	Read

Figure 28.7   E2FI Register

E²dataFlash Data Register [1]

b15 b8 b7 b0		

Symbol	Address	Reset Value
E2FD	44FEDh-44FECh	Undefined

Function	Setting Range	RW
After a read command, the data of the address written to the E2FA register is read. After a program command, the data set to this register is written to the address set to the E2FA register [2]	0000h to FFFFh (when ECC disabled) 0000h to 00FFh (when ECC enabled)	RW

Notes:
1. A 16-bit write/read access to this register should be performed.
2. In a program command operation, write this register after setting 0040h to the E2FI register.

Figure 28.8   E2FD Register

28.2   Block Configuration

The E^{2}dataFlash consists of 32 bytes x 128 blocks of flash memory when ECC is disabled, and 16 bytes x 128 blocks when ECC is enabled (refer to Figure 28.9 for details).

Figure 28.9   E^{2}dataFlash Memory Configuration

28.3   Operational Procedures

Figures 28.10 to 28.13 show the read, program, block erase, and clear status operational procedures. Follow the procedures to operate each.
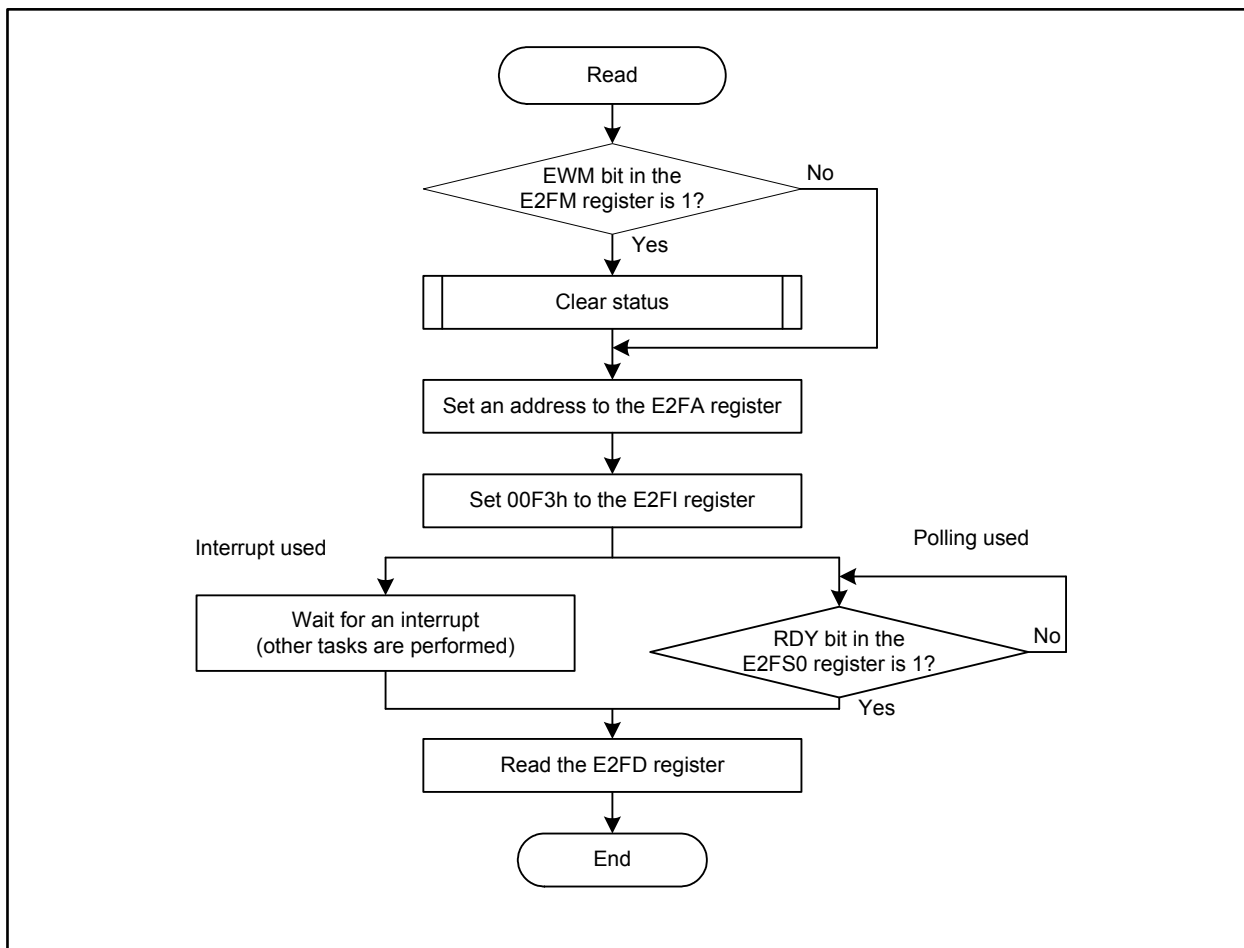

Figure 28.10 Read Operation
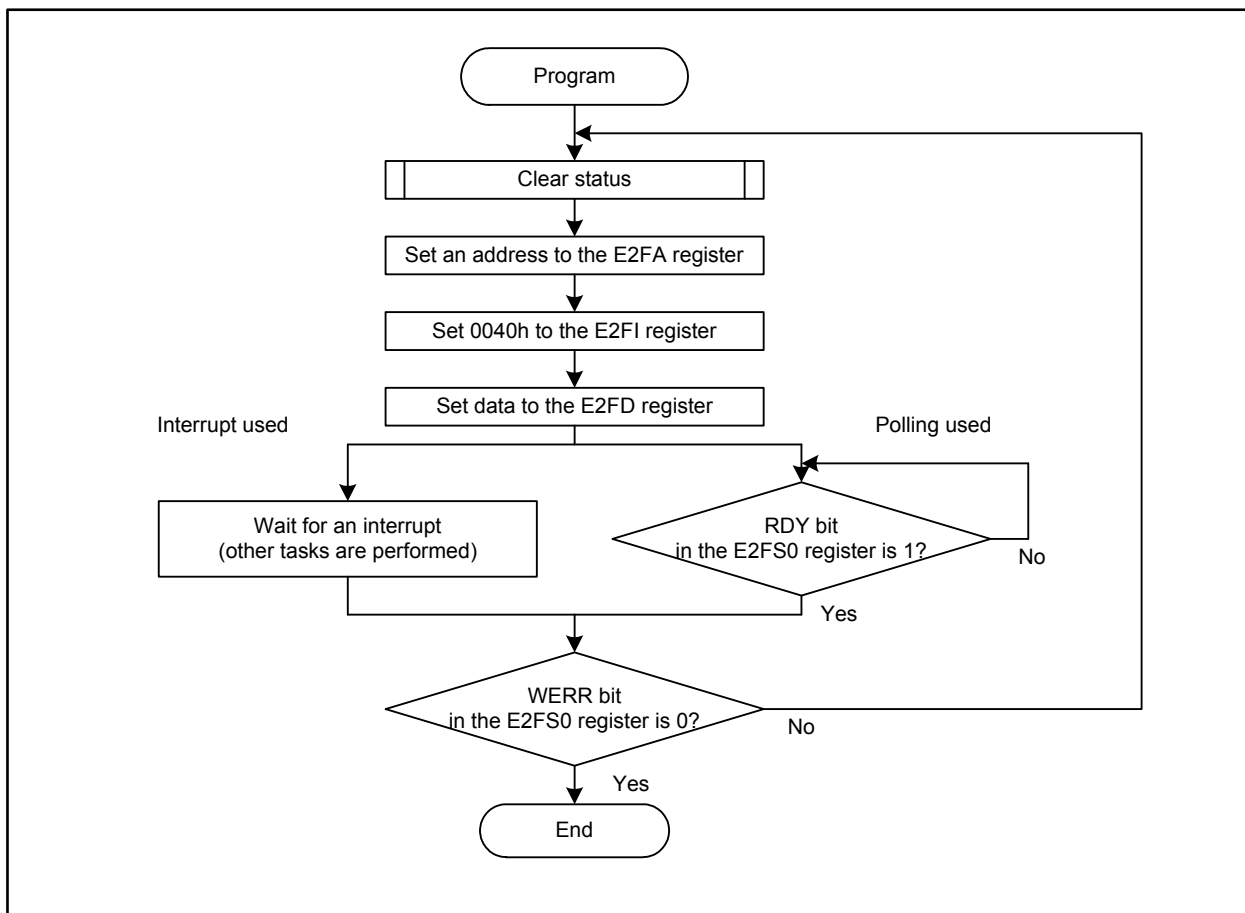

Figure 28.11 Program Operation
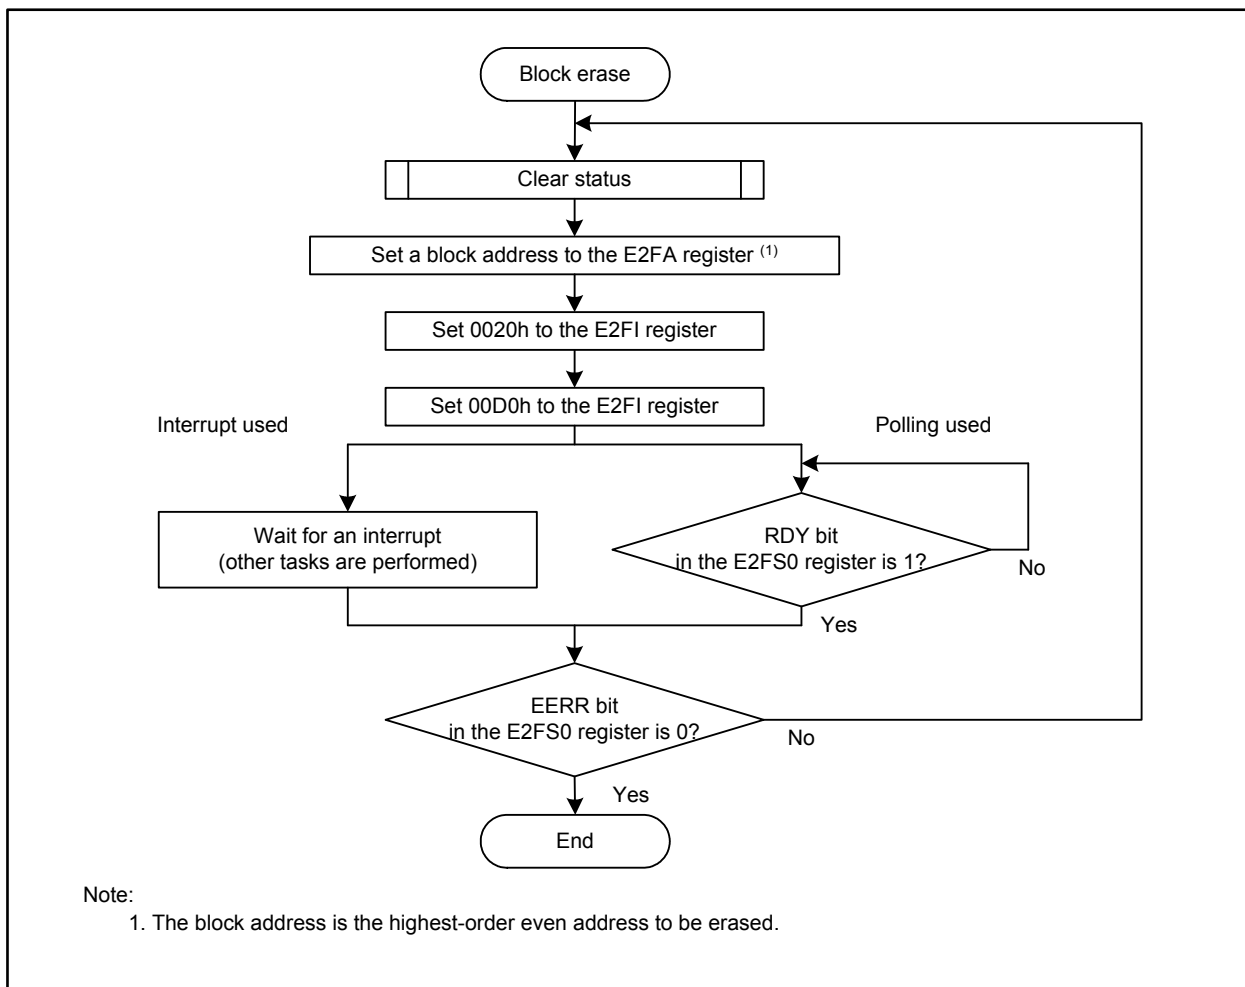

Figure 28.12 Block Erase Operation
Figure 28.13 Clear Status Operation

28.4   Note on E^{2}dataFlash

When the FEW bit in the FMCR register is 1 (CPU rewrite mode), do not set the EWM bit in the E2FM register to 1 (program or erase enabled).

29. Electrical Characteristics

Table 29.1   Absolute Maximum Ratings [1]

Symbol	Characteristic		Condition	Value	Unit
V_{CC}	Supply voltage		$V_{CC} = AV_{CC}$	-0.3 to 6.0	V
AV_{CC}	Analog supply voltage		$V_{CC} = AV_{CC}$	-0.3 to 6.0	V
V_I	Input voltage	XIN, $\overline{RESET}$, CNVSS, NSD, V_{REF}, P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7		-0.3 to V_{CC} + 0.3	V
V_O	Output voltage	XOUT, P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7		-0.3 to V_{CC} + 0.3	V
P_d	Power consumption		$T_a = 25°C$	500	mW
—	Operating temperature range			-40 to 125	°C
T_{stg}	Storage temperature range			-65 to 150	°C

Note:
1. Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 29.2   Operating Conditions (1/6) [1]

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
V_{CC}	Digital supply voltage		3.0	5.0	5.5	V
AV_{CC}	Analog supply voltage			V_{CC}		V
V_{REF}	Reference voltage		3.0		V_{CC}	V
V_{SS}	Digital ground voltage			0		V
AV_{SS}	Analog ground voltage			0		V
dV_{CC}/dt	V_{CC} ramp up rate (V_{CC} < 2.0 V)		0.05			V/ms
V_{IH}	High level input voltage	XIN, $\overline{RESET}$, CNVSS, NSD	$0.8 \times V_{CC}$		V_{CC}	V
		P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_7 [2], P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7	$0.7 \times V_{CC}$		V_{CC}	V
V_{IL}	Low level input voltage	XIN, $\overline{RESET}$, CNVSS, NSD	0		$0.2 \times V_{CC}$	V
		P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_7 [2], P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7	0		$0.3 \times V_{CC}$	V
T_{opr}	Operating temperature range	J version	-40		85	°C
		L version	-40		105	°C
		K version	-40		125	°C

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. V_{IH} and V_{IL} for P8_7 are specified for P8_7 as a programmable port. These values are not applicable for P8_7 as XCIN.

Table 29.3   Operating Conditions (2/6)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) [1]

Symbol	Characteristic		Value [2]			Unit
			Min.	Typ.	Max.	
C_{VDC}	Decoupling capacitance for voltage regulator	Inter-pin voltage: 1.5 V	2.4		10.0	µF

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. This value should be met with due consideration to the following conditions: operating temperature, DC bias, aging, etc.

Table 29.4   Operating Conditions (3/6)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) [1]

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
$I_{OH(peak)}$	High level peak output current [2]	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7			-10.0	mA
$I_{OH(avg)}$	High level average output current [3]	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7			-5.0	mA
$I_{OL(peak)}$	Low level peak output current [2]	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7			10.0	mA
$I_{OL(avg)}$	Low level average output current [3]	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_7, P8_0 to P8_4, P8_6, P8_7, P9_0 to P9_7, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_3 to P14_6, P15_0 to P15_7			5.0	mA

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. The following conditions should be satisfied:
    • The sum of $I_{OL(peak)}$ of ports P0, P1, P2, P8_6, P8_7, P9, P10, P11, P14, and P15 is 80 mA or less.
    • The sum of $I_{OL(peak)}$ of ports P3, P4, P5, P6, P7, P8_0 to P8_4, P12, and P13 is 80 mA or less.
    • The sum of $I_{OH(peak)}$ of ports P0, P1, P2, and P11 is -40 mA or less.
    • The sum of $I_{OH(peak)}$ of ports P8_6, P8_7, P9, P10, P14, and P15 is -40 mA or less.
    • The sum of $I_{OH(peak)}$ of ports P3, P4, P5, P12, and P13 is -40 mA or less.
    • The sum of $I_{OH(peak)}$ of ports P6, P7, and P8_0 to P8_4 is -40 mA or less.
3. Average value within 100 ms.

Table 29.5   Operating Conditions (4/6)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) [1]

Symbol	Characteristic	Value			Unit
		Min.	Typ.	Max.	
$f_{(XIN)}$	Main clock oscillator frequency	4		8	MHz
$f_{(XRef)}$	Reference clock frequency	2		4	MHz
$f_{(PLL)}$	PLL clock oscillator frequency	96		144	MHz
$f_{(Base)}$	Base clock frequency			64	MHz
$t_{c(Base)}$	Base clock cycle time	15.625			ns
$f_{(CPU)}$	CPU operating frequency			64	MHz
$t_{c(CPU)}$	CPU clock cycle time	15.625			ns
$f_{(BCLK)}$	Peripheral bus clock operating frequency			32	MHz
$t_{c(BCLK)}$	Peripheral bus clock cycle time	31.25			ns
$f_{(PER)}$	Peripheral clock source frequency			32	MHz
$f_{(XCIN)}$	Sub clock oscillator frequency		32.768	50	kHz

Note:
1. The device is operationally guaranteed under these operating conditions.
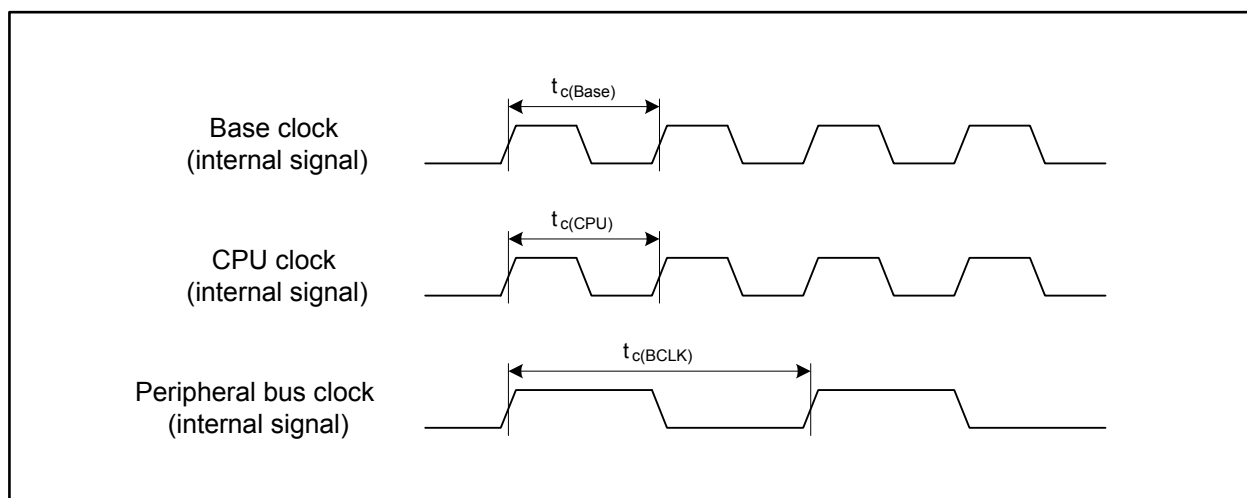

Figure 29.1   Clock Cycle Time

Table 29.6 **Operating Conditions (5/6)**
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) [1, 2]

Symbol	Characteristic		Measurement Condition	Value			Unit
				Min.	Typ.	Max.	
$I_{IC(H)}$	High input injection current	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_5, P7_7, P8_0 to P8_5, P9_1, P9_3 to P9_6, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7	$V_I > V_{CC}$			2	mA
$I_{IC(L)}$	Low input injection current	P0_0 to P0_7, P1_0 to P1_7, P2_0 to P2_7, P3_0 to P3_7, P4_0 to P4_7, P5_0 to P5_7, P6_0 to P6_7, P7_0 to P7_5, P7_7, P8_0 to P8_5, P9_1, P9_3 to P9_6, P10_0 to P10_7, P11_0 to P11_4, P12_0 to P12_7, P13_0 to P13_7, P14_1, P14_3 to P14_6, P15_0 to P15_7	$V_I < V_{SS}$			-2	mA
$\Sigma|I_{IC}|$	Total injection current					20	mA

Notes:
1. The device is operationally guaranteed under these operating conditions.
2. These conditions are applicable when each port is designated as input.

Table 29.7   Operating Conditions (6/6)
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and T_a = T_{opr}, unless otherwise noted) [1]

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
$V_{r(VCC)}$	Allowable ripple voltage	V_{CC} = 5.0 V			0.5	Vp-p
		V_{CC} = 3.0 V			0.3	Vp-p
$dV_{r(VCC)}/dt$	Ripple voltage gradient	V_{CC} = 5.0 V			±0.3	V/ms
		V_{CC} = 3.0 V			±0.3	V/ms
$f_{r(VCC)}$	Allowable ripple frequency				10	kHz

Note:
1.   The device is operationally guaranteed under these operating conditions.
Figure 29.2   Ripple Waveform

Table 29.8   Electrical Characteristics of Flash Memory
(V_{CC} = 3.0 to 5.5 V, V_{SS} = 0 V, and Ta = T_{opr}, unless otherwise noted)

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
—	Program/erase cycles [1]	Program area	1000			Cycles
		Data area	10000			Cycles
—	4-word program time	Program area		150	900	μs
		Data area		300	1700	μs
—	Lock bit program time	Program area		70	500	μs
		Data area		140	1000	μs
—	Block erasure time	4-Kbyte block		0.12	3.0	s
		32-Kbyte block		0.17	3.0	s
		64-Kbyte block		0.20	3.0	s
—	Data retention [2]	T_a = 55°C [3, 4]	20			Years

Notes:
1. Program/erase definition
   This value represents the number of erasures per block.
   When the number of program/erase cycles is n, each block can be erased n times.
   For example, if a 4-word write is performed in 512 different addresses in the 4-Kbyte block A and then the block is erased, this is counted as a single program/erase operation.
   However, the same address cannot be written to more than once per erasure (overwrite disabled).
2. Data retention includes periods when no supply voltage is applied and no clock is provided.
3. This data retention includes 3000 hours in T_a = 125°C and 7000 hours in T_a = 85°C.
4. Contact a Renesas Electronics sales office for data retention times other than the above condition.

Table 29.9   Electrical Characteristics of E2dataFlash
(V_CC = 3.0 to 5.5 V, V_SS = 0 V, and T_a = T_opr, unless otherwise noted)

Symbol	Characteristic		Value			Unit
			Min.	Typ.	Max.	
—	Program/erase cycles [1]		100000			Cycles
—	Word program time			100	2000	µs
—	Block erasure time	32 byte block		15	200	ms
t_{PS}	Flash memory circuit start-up stabilization time			35	50	µs
—	Data retention [2]	$T_a = 55°C$ [3, 4]	20			Years

Notes:
1. Program/erase definition
    This value represents the number of erasure per block.
    When the number of program/erase cycles is n, each block can be erased n times.
    For example, if a word write is performed in 16 different addresses in a block and then the block is erased, this is counted as a single program/erase operation. However, the same address cannot be written to more than once per erasure (overwrite disabled).
2. Data retention includes periods when no supply voltage is applied and no clock is provided.
3. This data retention includes 3000 hours in $T_a = 125°C$ and 7000 hours in $T_a = 85°C$.
4. Contact a Renesas Electronics sales office for data retention times other than the above condition.

Table 29.10   Power Supply Circuit Timing Characteristics
(V_CC = 3.0 to 5.5 V, V_SS = 0 V, and T_a = T_opr, unless otherwise noted)

Symbol	Characteristic	Measurement Condition	Value			Unit

30. Usage Notes

30.1   Notes on Board Designing

30.1.1   Power Supply Pins

The board should be designed so there is no potential difference between pins with the same name. Note the following points:
- Connect all VSS pins to the same GND. Traces for the pins should be as wide as physically possible so the same voltage can be applied to every VSS pin.
- Connect all VCC pins to the same power supply. Traces for the pins should be as wide as physically possible so the same voltage can be applied to every VCC pin.

Insert a capacitor between each VCC pin and the VSS pin to prevent operation errors due to noise. The capacitor should be beneficially effective at high and low frequencies and should have a capacitance of approximately 0.1 μF. The traces for the capacitor and the power supply pins should be as short and wide as physically possible.

30.1.2   Supply Voltage

The device is operationally guaranteed under operating conditions specified in electrical characteristics.
Drive the $\overline{\text{RESET}}$ pin low before the supply voltage becomes lower than the recommended value.

30.2   Notes on Register Setting

30.2.1   Registers with Write-only Bits

Read-modify-write instructions cannot be used when setting a register containing write-only bits. Read-modify-write instructions read a value of an address, modify the value, and write the modified value to the same address. Table 30.1 lists read-modify-write instructions, and Table 30.2 lists registers containing write-only bits. To set a new value by modifying the previous one, write the previous value into RAM as well as to the register, change the contents of the RAM and then transfer the new value to the register by the MOV instruction.

Table 30.1   Read-modify-write Instructions

Function	Mnemonic
Transfer	MOV*Dir*
Bit processing	BCLR, BM*Cnd*, BNOT, BSET, BTSTC, and BTSTS
Shifting	ROLC, RORC, ROT, SHA, and SHL
Arithmetic operation	ABS, ADC, ADCF, ADD, ADSF, DEC, DIV, DIVU, DIVX, EXTS, EXTZ, INC, MUL, MULU, NEG, SBB, and SUB
Decimal operation	DADC, DADD, DSBB, and DSUB
Floating-point operation	ADDF, DIVF, MULF, and SUBF
Logical operation	AND, NOT, OR, and XOR

Table 30.2   Registers with Write-only Bits

Module	Register	Symbol	Address
Watchdog timer	Watchdog timer start register	WDTS	04404Eh
Timer A	Timer A0 register [1]	TA0	0347h-0346h
	Timer A1 register [1]	TA1	0349h-0348h
	Timer A2 register [1]	TA2	034Bh-034Ah
	Timer A3 register [1]	TA3	034Dh-034Ch
	Timer A4 register [1]	TA4	034Fh-034Eh
	Increment/decrement select register	UDF	0344h

	UART1 transmit buffer register	U1TB	02EBh-02EAh
	UART2 transmit buffer register	U2TB	033Bh-033Ah
	UART3 transmit buffer register	U3TB	01E3h-01E2h
	UART4 transmit buffer register	U4TB	01EBh-01EAh
CAN module	CAN0 receive FIFO pointer control register	C0RFPCR	047F49h
	CAN0 transmit FIFO pointer control register	C0TFPCR	047F4Bh
	CAN1 receive FIFO pointer control register	C1RFPCR	047B49h
	CAN1 transmit FIFO pointer control register	C1TFPCR	047B4Bh

Note:
1.   The register has write-only bits in one-shot timer mode and pulse-width modulation mode.

30.3   Notes on Clock Generator

30.3.1   Sub Clock

30.3.1.1   Oscillator Constant Matching

The constant matching of the sub clock oscillator should be evaluated in both cases when the drive strength is high and low.
Contact the oscillator manufacturer for details on the oscillation circuit constant matching.

30.3.2   Power Control

Do not switch the base clock source until the oscillation of the clock to be used has stabilized. However, this does not apply to the on-chip oscillator since it starts running immediately after the CM31 bit in the CM3 register is set to 1.
To switch the base clock source from the PLL clock to a low speed clock, use the MOV.L or OR.L instruction to set the BCS bit in the CCR register to 1.

- Program example in assembly language
         OR.L   #80h, 0004h

- Program example in C language
         asm("OR.L #80h, 0004h");

30.3.2.1   Stop Mode

- To exit stop mode using a reset, apply a low signal to the $\overline{\text{RESET}}$ pin until the main clock oscillation stabilizes.

30.3.2.2   Suggestions for Power Saving

The following are suggestions to reduce power consumption when programming or designing systems.

- I/O pins:
  If inputs are floating, both transistors may be conducting. Set unassigned pins to input mode and connect each of them to VSS via a resistor, or set them to output mode and leave them open.
- A/D converter:
  When not performing the A/D conversion, set the VCUT bit in the AD0CON1 register to 0 (VREF disconnected). To perform the A/D conversion, set the VCUT bit to 1 (VREF connected) and wait at least 1 µs before starting conversion.
- D/A converter:
  When not performing the D/A conversion, set the DAiE bit in the DACON register (i = 0, 1) to 0 (output disabled) and the DAi register to 00h.
- Peripheral clock stop:
  When entering wait mode, power consumption can be reduced by setting the CM02 bit in the CM0 register to 1 to stop the peripheral clock source. However, this setting does not stop the fC32.

30.4   Notes on Interrupts

30.4.1   ISP Setting

The interrupt stack pointer (ISP) is initialized to 00000000h after a reset. Set a value to the ISP before an interrupt is accepted, otherwise the program may go out of control. A multiple of 4 should be set to the ISP, which enables faster interrupt sequence due to less memory access.

When using NMI, in particular, since this interrupt cannot be disabled, set the PM24 bit in the PM2 register to 1 (NMI enabled) after setting the ISP at the beginning of the program.

30.4.2   NMI

- NMI cannot be disabled once the PM24 bit in the PM2 register is set to 1 (NMI enabled). This bit setting should be done only when using NMI.

- When the PM24 bit in the PM2 register is 1 (NMI enabled), the P8_5 bit in the P8 register is enabled just for monitoring the $\overline{\text{NMI}}$ pin state. It is not enabled as a general port.

30.4.3   External Interrupts

- The input signal to the $\overline{\text{INTi}}$ pin requires the pulse width specified in the electrical characteristics (i = 0 to 8). If the pulse width is narrower than the specification, an external interrupt may not be accepted.

- When the effective level or edge of the $\overline{\text{INTi}}$ pin (i = 0 to 8) is changed by the following bits: bits POL, LVS in the INTiIC register, the IFSR0i bit (i = 0 to 5) in the IFSR0 register, and the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register, the corresponding IR bit may become 1 (interrupt requested). When setting the above mentioned bits, preset bits ILVL2 to ILVL0 in the INTiIC register to 000b (interrupt disabled). After setting the above mentioned bits, set the corresponding IR bit to 0 (no interrupt requested), then rewrite bits ILVL2 to ILVL0.

- The interrupt input signals to pins $\overline{\text{INT6}}$ to $\overline{\text{INT8}}$ are also connected to bits INT6R to INT8R in registers IIO9IR to IIO11IR. Therefore, these input signals, when assigned to the intelligent I/O, can be used as a source for exiting wait mode or stop mode. Note that these signals are enabled only on the falling edge and not affected by the following bit settings: bits POL and LVS in the INTiIC register (i = 0 to 8), IFSR0i bit (i = 0 to 5) in the IFSR0 register, and the IFSR1j bit (j = i - 6; i = 6 to 8) in the IFSR1 register.

30.5   Notes on DMAC

30.5.1   DMAC-associated Register Settings

- Set DMAC-associated registers while bits MDi1 and MDi0 in the DMDi register are 00b (DMA transfer disabled) (i = 0 to 3). Then, set bits MDi1 and MDi0 to 01b (single transfer) or 11b (repeat transfer) at the end of the setup procedure. This procedure also applies when rewriting bits UDAi, USAi, and BWi1 and BWi0 in the DMDi register.

- When rewriting the DMAC-associated registers while DMA transfer is enabled, stop the peripherals that can be DMA triggers so that no DMA transfer request is generated, then set bits MDi1 and MDi0 in the DMDi register of the corresponding channel to 00b (DMA transfer disabled).

- Once a DMA transfer request is accepted, DMA transfer cannot be disabled even if setting bits MDi1 and MDi0 in the DMDi register to 00b (DMA transfer disabled). Do not change the settings of any DMAC-associated registers other than bits MDi1 and MDi0 until the DMA transfer is completed.

- After setting registers DMiSL and DMiSL2, wait at least six peripheral bus clocks to set bits MDi1 and MDi0 in the DMDi register to 01b (single transfer) or 11b (repeat transfer).

30.5.2   Reading DMAC-associated Registers

- Use the following read order to sequentially read registers DMiSL and DMiSL2:
  DM0SL, DM1SL, DM2SL, and DM3SL
  DM0SL2, DM1SL2, DM2SL2, and DM3SL2

30.6   Notes on Timers

30.6.1   Timer A and Timer B

All timers are stopped after a reset. To restart timers, configure parameters such as operating mode, count source, and counter value, then set the TAiS bit or TBjS bit in the TABSR or TBSR register to 1 (count starts) (i = 0 to 4; j = 0 to 5).

The following registers and bits should be set while the TAiS bit or TBjS bit is 0 (count stops):
   • Registers TAiMR and TBjMR
   • UDF register
   • Bits TAZIE, TA0TGL, and TA0TGH in the ONSF register
   • TRGSR register

30.6.2   Timer A

30.6.2.1   Timer Mode

• While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

30.6.2.2   Event Counter Mode

• While the timer counter is running, the TAi register indicates a counter value at any given time. However, FFFFh is read if the timer counter underflows or 0000h if overflows while reloading is in progress. A set value is read if the TAi register is set while the timer counter is stopped.

30.6.2.3   One-shot Timer Mode

• If the TAiS bit in the TABSR register is set to 0 (count stops) while the timer counter is running, the following operations are performed:
   - The timer counter stops and the setting value of the TAi register is reloaded.
   - A low signal is output at the TAiOUT pin.
   - The IR bit in the TAiIC register becomes 1 (interrupts requested) after one CPU clock cycle.

• The one-shot timer is operated by an internal count source. When the trigger is an input to the TAiIN pin, the signal is output with a maximum one count source clock delay after a trigger input to the TAiIN pin.

• The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt, set the IR bit to 0 after one of the settings below is done:
   - Select one-shot timer mode after a reset.
   - Switch operating modes from timer mode to one-shot timer mode.
   - Switch operating modes from event counter mode to one-shot timer mode.

• If a retrigger occurs while counting, the timer counter decrements by one, reloads the setting value of the TAi register, and then continues counting. To generate a retrigger while counting, wait at least one count source cycle after the last trigger is generated.

• When an external trigger input is selected to start counting in timer A one-shot mode, do not provide an external retrigger for 300 ns before the timer counter reaches 0000h. Otherwise, it may stop counting.

30.6.2.4   Pulse-width Modulation Mode

- The IR bit becomes 1 by any of the settings below. To use the timer Ai interrupt, set the IR bit to 0 after one of the settings below is done (i = 0 to 4):
  - Select pulse-width modulation mode after a reset.
  - Switch operating modes from timer mode to pulse-width modulation mode.
  - Switch operating modes from event counter mode to pulse-width modulation mode.

- If the TAiS bit in the TABSR register is set to 0 (count stops) while PWM pulse is output, the following operations are performed:
  - The timer counter stops.
  - The output level at the TAiOUT pin changes from high to low. The IR bit becomes 1.
  - When a low signal is output at the TAiOUT pin, it does not change. The IR bit does not change, either.

30.6.3   Timer B

30.6.3.1   Timer Mode and Event Counter Mode

- While the timer counter is running, the TBj register indicates a counter value at any given time (j = 0 to 5). However, FFFFh is read while reloading is in progress. When a value is set to the TBj register while the timer counter is stopped, if the TBj register is read before the count starts, the set value is read.

30.6.3.2   Pulse Period/Pulse-width Measure Mode

- To set the MR3 bit in the TBjMR register to 0 (no overflow), write the TBjMR register after the MR3 bit becomes 1 (overflow) and at least one count source cycle has elapsed while the TBjS bit in the TABSR or TBSR register is 1 (start counter).

- Use the IR bit in the TBjIC register to detect overflow. The MR3 bit is used only to determine an interrupt request source within the interrupt handler.

- The counter value is undefined when the timer counter starts. Therefore, the timer counter may overflow before a measured pulse is applied on the initial valid edge and cause a timer Bj interrupt request to be generated.

- When the measured pulse is applied on the initial valid edge after the timer counter starts, an undefined value is transferred to the reload register. At this time, a timer Bj interrupt request is not generated.

- The IR bit may become 1 (interrupt requested) by changing bits MR1 and MR0 in the TBjMR register after the timer counter starts. However, if the same value is rewritten to bits MR1 and MR0, the IR bit does not change.

- Pulse width is continuously measured in pulse-width measure mode. Whether the measurement result is high-level width or not is determined by a program.

- When an overflow occurs at the same time a pulse is applied on the valid edge, this pulse is not recognized since an interrupt request is generated only once. Do not let an overflow occur in pulse period measure mode.

- In pulse-width measure mode, determine whether an interrupt source is a pulse applied on the valid edge or an overflow by reading the port level in the timer Bj interrupt handler.

30.7   Notes on Three-phase Motor Control Timers

30.7.1   Shutdown

- When a low signal is applied to the $\overline{\text{NMI}}$ pin with the following bit settings, pins TA1OUT, TA2OUT, and TA4OUT become high-impedance: the PM24 bit in the PM2 register is 1 (NMI enabled), the SDE bit in the IOBC register is 1 (shutdown enabled), the INV02 bit in the INVC0 register is 1 (three-phase motor control timers used), and the INV03 bit is 1 (three-phase motor control timer output enabled).

30.7.2   Register Setting

- Do not write to the TAi1 register before and after timer B2 underflows (i = 1, 2, 4). Before writing to the TAi1 register, read the TB2 register to verify that sufficient time remains until timer B2 underflows. Then, immediately write to the TAi1 register so no interrupt handling is performed during this write procedure. If the TB2 register indicates little time remains until the underflow, write to the TAi1 register after timer B2 underflows.

30.8   Notes on Serial Interface

30.8.1   Changing the UiBRG Register (i = 0 to 4)

- Set the UiBRG register after setting bits CLK1 and CLK0 in the UiC0 register. When these bits are changed, the UiBRG register must be set again.
- When a clock is input immediately after the UiBRG register is set to 00h, the counter may become FFh. In this case, it requires extra 256 clocks to reload 00h to the register. Once 00h is reloaded, the counter performs the operation without dividing the count source according to the setting.

30.8.2   Synchronous Serial Interface Mode

30.8.2.1   Selecting an External Clock

- If an external clock is selected, the following conditions must be met while the external clock is held high when the CKPOL bit in the UiC0 register is 0 (transmit data output on the falling edge of the transmit/receive clock and receive data input on the rising edge), or while the external clock is held low when the CKPOL bit is 1 (transmit data output on the rising edge of the transmit/receive clock and receive data input on the falling edge) (i = 0 to 4):
  - The TE bit in the UiC1 register is 1 (transmission enabled).
  - The RE bit in the UiC1 register is 1 (reception enabled). This bit setting is not required when only transmitting.
  - The TI bit in the UiC1 register is 0 (data held in the UiTB register).

30.8.2.2   Receive Operation

- In synchronous serial interface mode, the transmit/receive clock is controlled by the transmit control circuit. Set UARTi-associated registers for a transmit operation, even if the MCU is used only for receive operation (i = 0 to 4). Dummy data is output from the TXDi pin while receiving when the TXDi pin is set to output mode.

- When data is received continuously, an overrun error occurs when the RI bit in the UiC1 register is 1 (data held in the UiRB register) and the seventh bit of the next data is received in the UARTi receive shift register. Then, the OER bit in the UiRB register becomes 1 (overrun error occurred). In this case, the UiRB register becomes undefined. If an overrun error occurs, the IR bit in the SiRIC register does not change to 1.

30.8.3   Special Mode 1 (I^{2}C Mode)

- To generate a START condition, STOP condition, or repeated START condition, set the STSPSEL bit in the UiSMR4 register to 0 (i = 0 to 2). Then, wait at least a half clock cycle of the transmit/receive clock to change the condition generate bits (STAREQ, RSTAREQ, or STPREQ bit) from 0 to 1.

30.8.4   Reset Procedure on Communication Error

Operations which result in communication errors such as rewriting function select registers during transmission/reception should not be performed. Follow the procedure below to reset the internal circuit once the communication error occurs in the following cases: when the operation above is performed by a receiver or transmitter or when a bit slip is caused by noise.

  A. Synchronous Serial Interface Mode
  (1) Set the TE bit in the UiC1 register to 0 (transmission disabled) and the RE bit to 0 (reception disabled) (i = 0 to 4).
  (2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
  (3) Set bits SMD2 to SMD0 in the UiMR register to 001b (synchronous serial interface mode).
  (4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

  B. UART Mode
  (1) Set the TE bit in the UiC1 register to 0 (transmission disabled) and the RE bit to 0 (reception disabled).
  (2) Set bits SMD2 to SMD0 in the UiMR register to 000b (serial interface disabled).
  (3) Set bits SMD2 to SMD0 in the UiMR register to 100b (UART mode, 7-bit character length), 101b (UART mode, 8-bit character length), or 110b (UART mode, 9-bit character length).
  (4) Set the TE bit in the UiC1 register to 1 (transmission enabled) and the RE bit to 1 (reception enabled) if necessary.

30.9 Notes on A/D Converter

30.9.1 Notes on Designing Boards

- Three capacitors should be placed between the AVSS pin and pins such as AVCC, VREF, and analog inputs (AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, and AN15_0 to AN15_7) to avoid erroneous operations caused by noise or latchup, and to reduce conversion errors. Figure 30.1 shows an example of pin configuration for A/D converter.

Notes:
1. C1 ≥ 0.47 µF, C2 ≥ 0.47 µF, and C3 ≥ 100 pF (reference values)
2. The traces for the capacitor and the MCU should be as short and wide as physically possible.
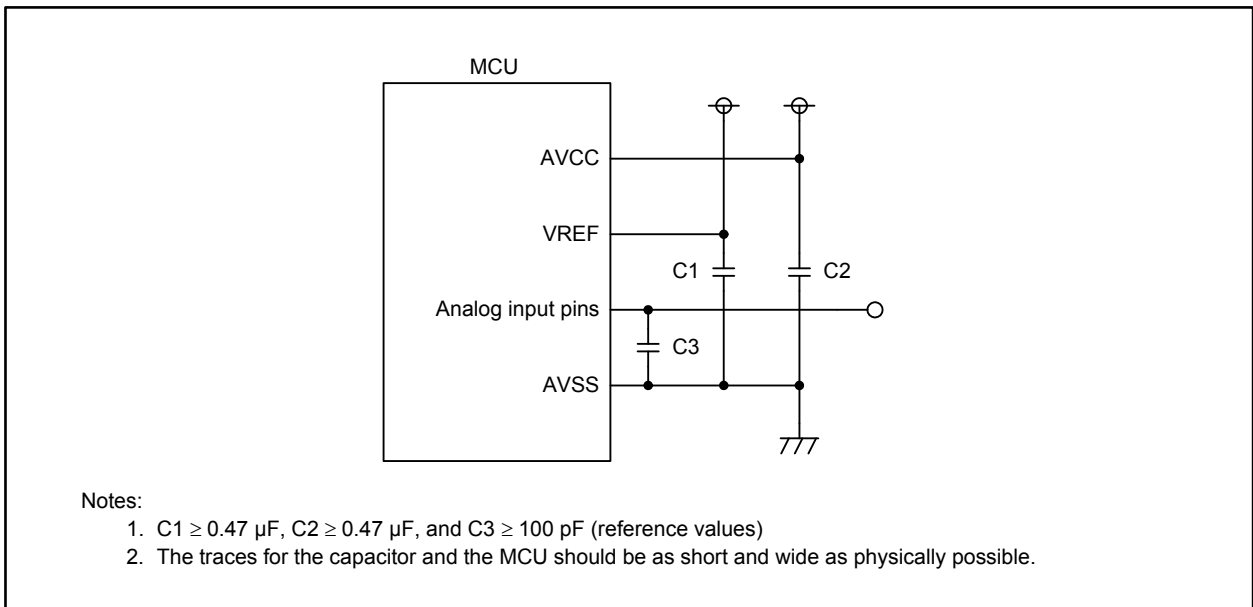

Figure 30.1   Pin Configuration for the A/D Converter

- Do not use AN_4 to AN_7 for analog input if the key input interrupt is to be used. Otherwise, a key input interrupt request occurs when the A/D input voltage becomes VIL or lower.

- When AVCC = VREF = VCC, A/D input voltage for pins AN_0 to AN_7, AN0_0 to AN0_7, AN2_0 to AN2_7, AN15_0 to AN15_7, ANEX0, and ANEX1 should be VCC or lower.

30.9.2   Notes on Programming

- The following registers should be written while A/D conversion is stopped. That is, before a trigger occurs: AD0CON0 (except the ADST bit), AD0CON1, AD0CON2, AD0CON3, AD0CON4, and AD0CON5.

- When the VCUT bit in the AD0CON1 register is changed from 0 (VREF connected) to 1 (VREF disconnected), wait for at least 1 µs before starting A/D conversion. When not performing A/D conversion, set the VCUT bit to 0 to reduce power consumption.

- Set the port direction bit for the pin to be used as an analog input pin to 0 (input). Set the ASEL bit of the corresponding port function select register to 1 (port is used as A/D input).

- When the TRG bit in the AD0CON0 register is 1 (external trigger or hardware trigger), set the corresponding port direction bit (PD9_7 bit) for the $\overline{\text{ADTRG}}$ pin to 0 (input).

- The φAD frequency should be 16 MHz or lower when VCC is 4.2 to 5.5 V, and 10 MHz or lower when VCC is 3.0 to 4.2 V. It should be 1 MHz or higher when the sample and hold function is enabled. If not, it should be 250 kHz or higher.

- When A/D operating mode (bits MD1 and MD0 in the AD0CON0 register or the MD2 bit in the AD0CON1 register) has been changed, reselect analog input pins by setting bits CH2 to CH0 in the AD0CON0 register or bits SCAN1 and SCAN0 in the AD0CON1 register.

- If the AD0i register is read when the A/D converted result is stored to the register, the stored value may have an error (i = 0 to 7). Read the AD0i register after A/D conversion is completed.
  In one-shot mode or single sweep mode, read the AD0i register after the IR bit in the AD0IC register becomes 1 (interrupt requested).
  In repeat mode, repeat sweep mode 0, or repeat sweep mode 1, an interrupt request can be generated each time A/D conversion is completed when the DUS bit in the AD0CON3 register is 1 (DMAC operating mode enabled). Similar to the other modes above, read the AD00 register after the IR bit in the AD0IC register becomes 1 (interrupt requested).

- When an A/D conversion is halted by setting the ADST bit in the AD0CON0 register to 0, the converted result is undefined. In addition, the unconverted AD0i register may also become undefined. Consequently, the AD0i register should not be used just after A/D conversion is halted.

- External triggers cannot be used in DMAC operating mode. When the DMAC is configured to transfer converted results, do not read the AD00 register by a program.

- While in single sweep mode, if A/D conversion is halted by setting the ADST bit in the AD0CON0 register to 0 (A/D conversion is stopped), an interrupt request may be generated even though the sweep is not completed. To halt A/D conversion, disable interrupts before setting the ADST bit to 0.

30.10   Note on Serial Bus Interface

30.10.1   Note on Synchronous Serial Communication Mode and 4-wire Serial Bus Mode

30.10.1.1 Accessing SBI Associated Registers

To read the SBI associated registers (44F06h to 44F2Fh), insert at least three instructions after writing to the registers.

- An example of inserting at least three instructions
  Program example   MOV.B   #00h, 44F0Bh ; Set the SS0ER register to 00h.
                                          NOP
                                          NOP
                                          NOP
                                          MOV.B   44F0Bh, R0L

30.11 Notes on Flash Memory Rewriting

30.11.1 Note on Power Supply

- Keep the supply voltage constant within the range specified in the electrical characteristics while a rewrite operation on the flash memory is in progress. If the supply voltage goes beyond the guaranteed value, the device cannot be guaranteed.

30.11.2 Note on Hardware Reset

- Do not perform a hardware reset while a rewrite operation on the flash memory is in progress.

30.11.3 Note on Flash Memory Protection

- If an ID code written in an assigned address has an error, any read/write operation on the flash memory in standard serial I/O mode is disabled.

30.11.4 Notes on Programming

- Do not set the FEW bit in the FMCR register to 1 (CPU rewrite mode) in low speed mode or low power mode.
- When the EWM bit in the E2FM register is 1 (program or erase enabled), do not set the FEW bit in the FMCR register to 1.
- The program, block erase, lock bit program, and protect bit program are interrupted by an NMI, a watchdog timer interrupt, an oscillator stop detection interrupt, or a low voltage detection interrupt. If any of the software commands above are interrupted, erase the corresponding block and then execute the same command again. If the block erase command is interrupted, the lock bit and protect bit values become undefined. Therefore, disable the lock bit, and then execute the block erase command again.

30.11.5 Notes on Interrupts

- EW0 mode
  - To use interrupts assigned to the relocatable vector table, the vector table should be addressed in RAM space.
  - When an NMI, watchdog timer interrupt, oscillator stop detection interrupt, or low voltage detection interrupt occurs, the flash memory module automatically enters read array mode. Therefore, these interrupts are enabled even during a rewrite operation. However, the rewrite operation in progress is aborted by the interrupts and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.
  - Instructions BRK, INTO, and UND, which refer to data on the flash memory, cannot be used in this mode.

- EW1 mode
  - Interrupts assigned to the relocatable vector table should not be accepted during program or block erase operation.
  - The watchdog timer should not be used in count source protect mode. The watchdog timer interrupt should not be generated.
  - When an NMI, watchdog timer interrupt, oscillator stop detection interrupt, or low voltage detection interrupt occurs, the flash memory module automatically enters read array mode. Therefore, these interrupts are enabled even during a rewrite operation. However, the rewrite operation in progress is aborted by the interrupts and registers FMR0 and FRSR0 are reset. When the interrupt handler has ended, set the EWM bit in the FMR0 register to 1 (EW1 mode) and the LBD bit in the FMR1 register to 1 (lock bit protection disabled) to re-execute the rewrite operation.

30.11.6 Notes on Rewrite Control Program

- EW0 mode
  - If the supply voltage drops during the rewrite operation of blocks having the rewrite control program, the rewrite control program may not be successfully rewritten, and the rewrite operation itself may not be performed. In this case, perform the rewrite operation by serial programmer or parallel programmer.

- EW1 mode
  - Do not rewrite blocks having the rewrite control program.

30.11.7 Notes on Number of Program/Erase Cycles and Software Command Execution Time

- The time to execute software commands (program, block erase, lock bit program, and protect bit program) increases as the number of program/erase cycles increases. If the number of program/erase cycles exceeds the endurance value specified in the electrical characteristics, it may take an unpredictable amount of time to execute the software commands. The wait time for executing software commands should be set much longer than the execution time specified in the electrical characteristics.

30.11.8 Other Notes

- The minimum values of program/erase cycles specified in the electrical characteristics are the maximum values that can guarantee the initial performance of the flash memory. The program/erase operation may still be performed even if the number of program/erase cycles exceeds the guaranteed values.
- Chips repeatedly programmed and erased for debugging should not be used for commercial products.

30.12 Note on E^{2}dataFlash

When the FEW bit in the FMCR register is 1 (CPU rewrite mode), do not set the EWM bit in the E2FM register to 1 (program or erase enabled).

Appendix 1. Package Dimensions

JEITA Package Code	RENESAS Code	Previous Code	MASS[Typ.]
P-LQFP144-20x20-0.50	PLQP0144KA-A	144P6Q-A / FP-144L / FP-144LV	1.2g

NOTE)
1. DIMENSIONS "*1" AND "*2"
    DO NOT INCLUDE MOLD FLASH.
2. DIMENSION "*3" DOES NOT
    INCLUDE TRIM OFFSET.

Rev.	Date	Description	
		Page	Summary
1.01	Sep 30, 2009	—	Initial release
1.03	Feb 16, 2010	—	Second edition released
		—	This manual in general • Added a question mark to the sentence in diamond-shaped boxes of flowcharts (under Chapters 23, 27, and 28)
		—	**About This Manual** • Changed "Shortsheet" row in **1. Purpose and Target User** to "Datasheet"-associated descriptions
			Chapter 7. Clock Generator
		—	• Made minor text modifications to this chapter
		93	• Modified description for Note 3 of CM1 register in **Figure 7.4**
		112	• Updated procedures for entering wait mode in **7.7.2.2**
		115	• Updated procedures for entering stop mode in **7.7.3.1**
			Chapter 10. Interrupts
		—	• Made minor text modifications to this chapter
			Chapter 11. Watchdog Timer
		155	• Changed bit name "Watchdog Timer Prescaler Select Bit" in **Figure 11.5** to "Watchdog Timer On-chip Oscillator Prescaler Select Bit"
			Chapter 12. DMAC
		—	• Made minor text modifications to this chapter
		161	• Modified description "IFSR0 register" in line 2 of Note 1 for **Table 12.3** to "IFSR1 register"
			Chapter 13. DMACII
		176	• Modified the following typos in lines 9 and 10 of **13.3.1**: "001FFFFFh" to "01FFFFFFh", "00200000h" to "02000000h", and "00000000h" to "FE000000h"
			Chapter 15. Timers
		—	• Made minor text modifications to this chapter
			Chapter 17. Serial Interface
		—	• Made minor text modifications to this chapter
		240	• Modified expression "7 (, 8, and 9) -bit transfer data" for "Function" of UiMR register in **Figure 17.4** to "7 (, 8, and 9) -bit character length"
		250	• Modified description "(i = 0 to 2)" for "Transmit/receive clock" in **Table 17.2** to "(i = 0 to 4)"
		255, 264	• Deleted description "(i = 0 to 4)" from subsection B in **17.1.1** and **17.2.2**, respectively
		272	• Modified descriptions "UART transmit/UART receive interrupt" in (3) of **Figure 17.30** to "transmit/receive interrupt"
			Chapter 18. A/D Converter
		—	• Made minor text modifications to this chapter
		290	• Modified description for Note 5 of AD0CON3 register in **Figure 18.5**
		292	• Modified description for Notes 1 and 4 of AD0i register in **Figure 18.8**
		293-299	• Modified descriptively **Tables 18.2 to 18.8**

Rev.	Date	Description	
		Page	Summary
		306	• Added description to the ninth bullet point of **18.3.2**
			Chapter 23. Serial Bus Interface
		356	• Changed the following expressions in **Table 23.2**: "Transmit starting conditions" to "Transmit start conditions" and "Receive starting conditions" to "Receive start conditions"
			Chapter 24. LIN Module
		—	• Made minor text modifications to this chapter
		403	• Corrected a typo: "L0DB0" in the title of **Figure 24.18** to "L0DB1"
		407	• Modified the following descriptions: "LiEST register" in (4) of **Table 24.4** and "LiTC register" in (6) to "LEST regsiter" and "LTC register", respectively
		408	• Modified description "LiTC register" in (5) of **Table 24.5** to "LTC register"
		418	• Changed descriptions for some steps and Note 2 in **Figure 24.30**
		422	• Modified descriptions "Frame transmit completion flag" and "Frame transmit completion flag" in **Figure 24.32** to "Frame/wake-up transmit completion flag" and "Frame/wake-up receive completion flag", respectively
			Chapter 25. CAN Module
		—	• Made minor text modifications to this chapter
		433	• Corrected a typo "(b23-22)" for CiBCR register in **Figure 25.4** to "(b23-b22)"
		439	• Changed "*" as multiplication sign in **Table 25.4** to "×"
		444	• Modified register name "CANi Message Control Register" in the title of **25.1.9** to "CANi Message Control Register j"
		453	• Corrected a typo "TFE bit in the CiTFPCR register" in line 3 of **25.1.13** to "TFE bit in the CiTFCR register"
		461	• Modified description "CAFSR register" in lines 2 to 3 of **25.1.18** to "CiAFSR register"
			Chapter 26. I/O Pins
		—	• Made minor text modifications to this chapter
		497, 500, 501, 507-509, 511	• Modified description "IIOi_j output" for bits PSEL2 to PSEL0 in **Figures 26.4, 26.7, 26.8, 26.14 to 26.16, and 26.18** to "IIOi output"
		497, 500-503, 508	• Modified description "Serial bus k output" for bits PSEL2 to PSEL0 in **Figures 26.4, 26.7 to 26.10, and 26.15** to "SBIk output"
		516	• Changed bit name "Serial Bus i Input Pin Switch Bit" in **Figure 26.22** to "SBIi Input Pin Switch Bit" and respective Notes
		519	• Modified bit name "P7_2 and P7_3 Pull-Up Control Bit" in **Figure 26.27** to "P7_0 to P7_3 Pull-Up Control Bit"
			Chapter 27. Flash Memory
		—	• Made minor text modifications to this chapter
		552	• Modified description "erase operation" in the first bullet point of EW1 mode in **27.6.5** to "block erase operation"
			Chapter 29. Electrical Characteristics
		572	• Added two measurement conditions to **Table 29.13**

Rev.	Date	Description	
		Page	Summary
		578	• Changed expression "Sample time" for "Characteristic" of "t_{SAMP}" in **Table 29.19** to "Sampling time"
			Chapter 30. Usage Notes
		—	• Made minor text modifications to this chapter
		612	• Added description to the ninth bullet point of **30.9.2**
		614	• Modified description "erase operation" in the first bullet point of EW1 mode in **30.11.5** to "block erase operation"
1.10	Jan 21, 2011	—	Third edition released
		—	This manual in general • Applied new Renesas templates and formats to the manual • Changed company name to "Renesas Electronics Corporation" and changed related descriptions due to business merger of Renesas Technology Corporation and NEC Electronics Corporation (under Chapters 1 and 29) • Modified expressions "version J", "version L", and "version K" to "J version", "L version", and "K version", respectively (under Chapters 1 and 29)
			Chapter 1. Overview
		—	• Modified wording and enhanced description in this chapter
		2	• Modified "re-oscillation detection" in **Table 1.1** to "restart detection"
		4	• Completed all "under development" phases in **Table 1.3**
		7	• Revised **Figure 1.3**
		12	• Modified expression "fC" in **Table 1.8** to "low speed clocks"
			Chapter 2. CPU
		—	• Modified wording and enhanced description in this chapter
			Chapter 3. Memory
		—	• Modified wording and enhanced description in this chapter
			Chapter 4. SFRs
		—	• Made minor text modifications to this chapter
		25, 26, 28, 31	• Changed hexadecimal format of reset values for registers G1BCR0, G2BCR0, G0BCR0, and G3BCR0 in **Tables 4.6, 4.7, 4.9, and 4.12** to binary
		25, 28, 31	• Changed register name "Group i Timer Measurement Prescaler Register" in **Tables 4.6, 4.9, and 4.12** to "Group i Time Measurement Prescaler Register"
		32	• Modified expression "XY Control Register" in **Table 4.13** to "X-Y Control Register"
		34	• Changed register name "UART2 Transmission/Receive Mode Register" in **Table 4.15** to "UART2 Transmit/Receive Mode Register"; Changed hexadecimal format of reset values for registers TABSR, ONSF, and TRGSR to binary; Changed register name "Increment/Decrement Counting Select Register" for UDF to "Increment/Decrement Select Register"
		45	• Changed register name "External Interrupt Source Select Register i" in **Table 4.26** to "External Interrupt Request Source Select Register i"

Rev.	Date	Description	
		Page	Summary
		60-61, 74-75	• Modified register name "CANi Acceptance Mask Register k" in **Tables 4.41 to 4.42 and 4.55 to 4.56** to "CANi Mask Register k"
		63, 77	• Modified register names "CANi Reception Error Count Register" and "CANi Transmission Error Count Register" in **Tables 4.44 and 4.58** to "CANi Receive Error Count Register" and "CANi Transmit Error Count Register", respectively; Corrected reset value "XXXX XX00b" for registers C1MSMR and C0MSMR to "0000 0000b"
			Chapter 5. Resets
		—	• Modified wording and enhanced description in this chapter
		78	• Changed expression "operating level" in (2) of B in **5.1** to "operating voltage"
			Chapter 6. Power Management
		—	• Modified wording and enhanced description in this chapter
		82	• Modified descriptions "main clock oscillator active" and "PLL clock oscillator active" in Note 2 of **Figure 6.2** to "main clock oscillator enabled" and "PLL oscillator enabled"
		85	• Modified bit name of VDEN bit in **Figure 6.4** to "Low Voltage Detector Enable Bit"
		85, 87	• Modified function descriptions of VDEN bit in **Figure 6.4** and in line 2 of **6.2.1** to "low voltage detector disabled" when it is 0 and "low voltage detector enabled" when it is 1
			Chapter 7. Clock Generator
		—	• Modified wording and enhanced description in this chapter
			• Modified function descriptions of bits CM05 and CM10 to the following: "main clock oscillator enabled", "main clock oscillator disabled", "PLL oscillator enabled", and "PLL oscillator disabled"
		90	• Modified expression "fC" in **Figure 7.1** to "Low speed clock"; Modified "low speed clock" associated items
		91	• Deleted the last sentence from Note 2 in **Figure 7.2**; Added description for bit settings to Note 6
		92	• Modified expression "fC" in **Figure 7.3** to "low speed clock"; Modified Note 2; Added Note 7
		93	• Modified bit name of CM10 bit in **Figure 7.4** to "PLL Oscillator Stop Bit"; Added Note 4
			• Modified function descriptions of CM20 bit in **Figure 7.5** to "Disable oscillator stop detection" when it is 0 and "Enable oscillator stop detection" when it is 1
		94	• Added description to Note 1 in **Figure 7.6**
		96	• Modified the following function descriptions in Note 3 of **Figure 7.9**: "start main clock oscillator running" for CM05 bit to "main clock oscillator enabled/disabled" and "start PLL clock oscillator running" for CM10 bit to "PLL oscillator enabled/disabled"; Added Note 6
		97	• Added description to Note 1 in **Figure 7.10**
		101	• Changed SEO bit name and its function description in **Figure 7.15**
			• Added Note 1 to **Figure 7.16**
		104	• Added description of stopping main clock to lines 6 to 7 of **7.2.1**

Rev.	Date	Description	
		Page	Summary
		106, 114, 117	• Modified expression "fC" in line 1 of **7.6** to "Low speed clocks" and "fC" in **Tables 7.3, 7.4, and 7.6** to "low speed clock", respectively
		107	• Revised the entire paragraph of **7.7**
		108	• Revised **7.7.1** entirely
		110-112	• Moved Figures 7.18 to 7.20 into **7.7.1**
		110	• Corrected a typo "f(XPLL)" in the third row of **Figure 7.18** to "f(PLL)"; Deleted Note 4
		111	• Corrected a typo "CM0 = 1" in the fifth row of **Figure 7.19** to "CM05 = 1"; Deleted Note 3
		112	• Corrected "CM31 = 1" in the first row and "CM10 = 0" for "Low speed mode" in the second row of **Figure 7.20** to "CM31 = 0" and "CM10 = 1", respectively; Deleted Note 3
		114	• Revised **7.7.2.4**
		115	• Added Note 1 to **Table 7.5**
		116	• Modified description in line 1 of **7.7.3**
		117	• Added interrupt numbers 0 to 63 to line 2 of **7.7.3.3** as factors of exiting stop mode
			• Added usage condition to "External interrupt" in **Table 7.7**
			Chapter 8. Bus
		—	• Made minor text modifications to this chapter
			Chapter 9. Protection
		—	• Changed title of each sub chapter of this chapter
			Chapter 10. Interrupts
		—	• Made minor text modifications to this chapter
		144	• Deleted "Bits RLVL2 to RLVL0 in the RIPL2 register" and associated signal lines from **Figure 10.8**; Changed expression "DMAC II" to "DMA II transfer complete"
		151	• Changed function description of b0 in registers IIO0IR to IIO11IR in **Figure 10.17**; Modified description of Note 3 descriptively
		153	• Revised the third bullet point of description in **10.14.3**
			Chapter 11. Watchdog Timer
		155	• Added Notes 1 and 2 to **Figure 11.2**
		156	• Added Note 2 to **Figure 11.3**
		157	• Added Note 3 to **Figure 11.5**
			Chapter 12. DMAC
		—	• Made minor text modifications to this chapter
		159	• Modified expression "DMA transfer startup" in **Table 12.1** to "DMA transfer start-up"
		172	• Modified description "peripheral clocks" in the fourth bullet point of **12.4.1** to "peripheral bus clocks"
			Chapter 13. DMAC II
		173	• Corrected bit name "IIRLT" in the fifth bullet point of **13.1** to "IRLT"
			Chapter 15. Timers
		—	• Modified wording and enhanced description in this chapter
			• Modified expressions "increment counting" and "decrement counting" to "increment" and "decrement", respectively

Rev.	Date	Description	
		Page	Summary
		186	• Separated signal for overflow or underflow from interrupt signal in **Figure 15.2**
		190	• Deleted expression "Counting" from UDF register name and bit names for bits TA4UD to TA0UD in **Figure 15.7**
		200	• Corrected a typo "TA4NR" in line 3 of **15.1.3** to "TA4MR"
		214	• Modified Note 2 in **Figure 15.27**
			Chapter 16. Three-phase Motor Control Timers
		—	• Made minor text modifications to this chapter
		222	• Changed expressions "Timer A reload control signal is 0" and "Timer A reload control signal is 1" for INV13 bit in **Figure 16.3** to "Timer A1 reload control signal is 0" and "Timer A1 reload control signal is 1", respectively
		227	• Changed bit functions of bits MR2 and MR3 for register TB2MR in **Figure 16.8**
		228	• Changed function descriptions of PWCON bit for TB2SC register in **Figure 16.9**
		234	• Corrected bit "INV06" in Note 3 of **Figure 16.16** to "INV16"
		235	• Changed description of Case 1 for "INV00 = 1, and ICTB2 = 1h" in **Figure 16.18**
		237	• Added description of SDE bit to **16.6.1**; Modified text representation • Modified "overflow" in **16.6.2** to "underflow"
			Chapter 17. Serial Interface
		—	• Made minor text modifications to this chapter
		243	• Deleted Note 1 from **Figure 17.5**
		247, 249	• Deleted "of the SCLi" from descriptions for bits SWC and SWC9 in in **Figures 17.11 and 17.13**
		249, 275	• Corrected a typo "STARREQ" in Note 3 of **Figure 17.13** and line 1 of **17.3.2** to "STAREQ"
		250	• Modified Note 1 in **Figure 17.15**
		267, 268	• Changed expression "Transmit/receive clock" in **Figures 17.27 and 17.28** to "CLKi"
		277, 279, 283, 284	• Modified descriptions of bit functions in the following: lines 6, 9, 10, and 14 of **17.3.4**, lines 1 and 10 of **17.3.8**, line 2 of **17.4.2.1**, and line 2 of **17.4.2.2**
		285	• Moved description in the fourth dash in **17.5.2.1** to the second dash
		286	• Added new paragraph for "Reset Procedure on Communication Error" as **17.5.4**
			Chapter 18. A/D Converter
		—	• Modified wording and enhanced description in this chapter
		292	• Modified expression "sample & hold function" in **Figure 18.4** to "sample and hold function"
		295	• Changed Note 3 in **Figure 18.8**
		309	• Corrected register name "AD0i" in the ninth bullet point of **18.3.2** to "AD00"

Rev.	Date	Description	
		Page	Summary
			Chapter 20. CRC Calculator
		312	• Corrected a typo "CRC_CCITT" in line 2 of **20. CRC Calculator** to "CRC-CCITT"
			Chapter 21. X-Y Conversion
		315, 316	• Changed figure titles "XiR Register" and "YjR Register" for **Figures 21.2 and 21.3** to "Registers X0R to X15R" and "Registers Y0R to Y15R", respectively; Changed preposition "to" in between addresses to "-"
			Chapter 22. Intelligent I/O
		—	• Modified wording and enhanced description in this chapter
			• Modified expressions "increment counting" and "decrement counting" to "increment" and "decrement", respectively
		320-323	• Changed expressions "the $\overline{\text{INT0}}$ pin" in **Figure 22.1**, "the $\overline{\text{INT1}}$ pin" in **Figure 22.2**, "the $\overline{\text{INT2}}$ pin" in **Figure 22.3**, and "the $\overline{\text{INT3}}$ pin" in **Figure 22.4** to "the $\overline{\text{INT0}}$ pin or the $\overline{\text{INT1}}$ pin"
		326	• Changed expression "$\overline{\text{INTi}}$ pin" in **Figure 22.7** to "$\overline{\text{INT0}}/\overline{\text{INT1}}$ pin"; Modified bit name for bits UD1 and UD0 to "Incrementing/ Decrementing Control Bit"; Modified Note 3 descriptively
		327	• Deleted Note 3 from **Figure 22.8**
		334	• Modified description of "Reset conditions" in **Table 22.2**
		335	• Modified expression "$\overline{\text{INTk}}$ pin" in **Figure 22.17** to "the $\overline{\text{INT0}}/\overline{\text{INT1}}$ pin"; Moved "i = 0 to 3" to figure title
		336, 337	• Moved "(i = 0 to 3)" in **Figures 22.18 and 22.19** to respective figure titles
		342	• Moved "k = 4, 5" in **Figure 22.23** to its figure title
			Chapter 23. Serial Bus Interface
		—	• Modified wording and enhanced description in this chapter
			• Modified function descriptions of bits CE and ORER to "conflict error occurred" and "overrun error occurred" when they are 1, respectively
		356	• Corrected a typo "SBUMS bit" in **23. Serial Bus Interface** to "SSUMS bit"
		357, 359	• Corrected typos "SSiCK pin" and "SSiRDR register" in **Tables 23.1 and 23.2** to "SSCKi pin" and "SSiTDR register", respectively
		359	• Modified "SSIi (I): Data input pin" and "SSOi (O): Data output pin" in **Table 23.2** to "SSIi (I/O): Data I/O pin" and "SSOi (I/O): Data I/O pin", respectively
		363	• Added description "Bits left during transmission/reception" to "Function" of bits BC2 to BC0 in **Figure 23.5**
		367	• Modified descriptions "input/output pin" and "Input/output pin" in **Figure 23.9** to "I/O pin"
			Chapter 24. LIN Module
		—	• Modified wording and enhanced description in this chapter
		391	• Modified descriptions "Break dominant" and "Break delimiter" in **Table 24.1** to "Transmit break length" and "Transmit break delimiter length", respectively

Rev.	Date	Description	
		Page	Summary
		395	• Modified function descriptions of bits L3LD to L0LD in **Figure 24.3** to "The bit is read as the value of the LD bit in the LST register of channel i"; Added Note 1
		397	• Changed Note 4 in **Figure 24.7**
		400	• Modified bit names for bits BLT3 to BLT0 and bits BDT1 and BDT0 in **Figure 24.10** to "Transmit Break (Low) Length Setting Bit" and "Transmit Break Delimiter (High) Length Setting Bit", respectively
		405	• Added description to Note 1 in **Figure 24.16**; Added Note 3
		406	• Added description to Note 1 in **Figure 24.17**
		409	• Modified bits "BFTL3 to BFTL0" and "BFTD1 and BFTD0" in (1) of **Table 24.3** to "BLT3 to BLT0" and "BDT1 and BDT0", respectively
		410, 411	• Changed (4) for "LIN Module Processing" in **Tables 24.4 and 24.5**
		414	• Corrected a typo "BPR0" in Note 1 of **Table 24.6** to "BRP0"
		421	• Changed order of procedure in **Figure 24.30**
		422	• Added detecting condition to "Input signal low detection" in **Table 24.8**
		423	• Deleted j value from the title of **Table 24.9**
		425	• Added description to lines 9 to 10 in **24.11** • Modified **Figure 24.32**
		426	• Modified **Figure 24.33**
		Chapter 25. CAN Module	
		—	• Made minor text modifications to this chapter • Changed expression "8/3 encoder" to "8-to-3 priority encoder"
		427	• Modified "Table 25.1" in line 5 of **25. CAN Module** to "Table 25.1 and Table 25.2"
		439	• Modified Note 2 in **Figure 25.6** descriptively
		443	• Changed description "Setting Value" in **Figure 25.8** to "Setting Range"; Modified Note 4 descriptively
		450	• Modified Note 2 in **Figure 25.11** descriptively
		463	• Modified description in line 3 of **25.1.17**
		464	• Changed expression "3/8 decoder" in **Figure 25.23** to "3-to-8 decoder"; Moved "j = 0 to 31" to its figure title
		472	• Moved "(4)" from "Bit Name" to "Function" in **Figure 25.28**; Modified Note 4
		481	• Changed expression "MCU hardware reset or software reset" in line 2 of **25.2.3** to "a MCU reset"
		482	• Corrected a typo "CiSTR register" in the third bullet point of the third paragraph of **25.2.4** to "CiTCR register"
		484	• Corrected q value in **Figure 25.36** to "q = 2, 3, 4"
		Chapter 26. I/O Pins	
		496	• Deleted ASEL from a factor of pull-up resistor being separated from peripheral functions in **26. I/O Pins and Figure 26.1**
		500, 503, 504, 510-512, 514	• Changed expression "IIOj output" in **Figures 26.4, 26.7, 26.8, 26.14 to 26.16, and 26.18** to "IIOj_i output", respectively
		519	• Changed expression "serial bus i" in **Figure 26.22** to "SBIi"

Rev.	Date	Description	
		Page	Summary
		523	• Modified bit name "P14_1 to P14_3 Pull-Up Control Bit" in **Figure 26.29** to "P14_1 and P14_3 Pull-up Control Bit"
			Chapter 27. Flash Memory
		—	• Modified wording and enhanced description in this chapter
		529	• Deleted descriptions "erase" and "by using the serial programmer" from "ROM Code Protection" in **Table 27.3**; Added "erase" to "ID Code Protection"; Corrected a typo "diactivate" to "deactivate" • Deleted description "use the serial programmer to" from line 3 of **27.2.2**
		530	• Assigned "OFS" to the reserved ID code area in address FFFFFFEFh in **Figure 27.2**; Added Note 1
		532	• Changed the following expressions in **Table 27.5**: "the program or the block erase command" to "the program command or the block erase command" and "the read status register command" and "the ready status register command" to "the enter read status register mode command"
		538, 540	• Changed expressions "$\overline{CS0}$" and "A23 to A0, $\overline{BC3}$ to $\overline{BC0}$" in **Figures 27.12 and 27.13** to "Chip select" and "Address", respectively
		555	• Changed description "(erase/write enabled mode)" in the second bullet point of **27.6.4** to "(program or erase enabled)"
			Chapter 28. E^{2}PROM Emulation Data Flash
		—	• Modified wording and enhanced description in this chapter
		558	• Added description to Note 3 of **Figure 28.2**; Deleted description from Note 5
		560	• Corrected figure title "F2FI Register" for **Figure 28.7** to "E2FI Register"
		564	• Modified description for EERR bit setting in **Figure 28.12** to "EERR bit in the E2FS0 register is 0?"
			Chapter 29. Electrical Characteristics
		—	• Modified wording and enhanced description in this chapter • Changed expression "clock period" to "clock cycle time"
		577	• Changed expressions "$\overline{CS0}$" and "A23 to A0, $\overline{BC3}$ to $\overline{BC0}$" in **Figure 29.5** to "Chip select" and "Address", respectively
			Chapter 30. Usage Notes
		—	• Modified wording and enhanced description in this chapter
		603	• Corrected a typo "trances" in the first bullet point of **30.1.1** to "traces"
		604	• Deleted expression "counting" from UDF register name in **Table 30.1**
		607	• Revised the third bullet point of description in **30.4.3**
		608	• Modified description "peripheral clocks" in the fourth bullet point of **30.5.1** to "peripheral bus clocks"
		612	• Added description of SDE bit to **30.7.1**; Modified text representation • Modified "overflow" in **30.7.2** to "underflow"
		613	• Moved description in the fourth dash in **30.8.2.1** to the second dash

Rev.	Date	Description	
		Page	Summary
		614	• Added new paragraph for "Reset Procedure on Communication Error" as **30.8.4**
		616	• Corrected register name "AD0i" in the ninth bullet point of **30.9.2** to "AD00"
		618	• Changed description "(erase/write enabled mode)" in the second bullet point of **30.11.4** to "(program or erase enabled)"
		Appendix 1. Package Dimensions	
		621	• Added a seating plane to the drawing of package dimension
1.20	Sep 10, 2013	—	Fourth edition released
		—	This manual in general • Changed document number "REJ09B0506-0110" to "R01UH0222EJ0120"
		Chapter 1. Overview	
		—	• Modified wording and enhanced description in this chapter
		1	• Modified expression "I2C" in line 9 of **1.1** to "I2C-bus interface"
		2	• Modified expressions "calculation transfer" and "chained transfer" in **Table 1.1** to "calculation result transfer" and "chain transfer", respectively
		8, 10	• Changed the order of timer pins for pin no. 36 in **Table 1.4** and pin nos. 79 and 81 in **Table 1.6**
		13	• Modified expression "I2C bus" in **Table 1.9** to "I2C-bus"
		Chapter 2. CPU	
		—	• Modified wording and enhanced description in this chapter
		16	• Corrected a typo "R3R0" in line 3 of **2.1.1** to "R3R1"
		Chapter 5. Resets	
		—	• Modified wording and enhanced description in this chapter
		Chapter 6. Power Management	
		—	• Modified wording and enhanced description in this chapter
		87	• Modified description "the voltage rises above Vdet(R)" in line 7 of **6.2.1** to "the voltage rises to or above Vdet(R)"
		Chapter 7. Clock Generator	
		—	• Modified wording and enhanced description in this chapter
		90	• Added the BCS bit to **Figure 7.1**
		92	• Modified CM03 bit name "XCIN-XCOUT Drive Power Select Bit" in **Figure 7.3** to "XCIN-XCOUT Drive Strength Select Bit"
		93	• Modified bit name of the CM15 bit "XIN-XOUT Drive Power Select Bit" in **Figure 7.4** to "XIN-XOUT Drive Strength Select Bit": Modified description of Note 2 • Corrected a typo "CM02 bit" in Note 3 of **Figure 7.5** to "CM20 bit"
		103	• Modified the last sentence of **7.1.4**
		104	• Deleted the last sentence in parenthesis in **7.2**
		113	• Modified descriptions in lines 1 to 3 of **7.7.2**
		Chapter 8. Bus	
		—	• Modified wording and enhanced description in this chapter
		Chapter 9. Protection	
		—	• Modified wording and enhanced description in this chapter

Rev.	Date	Description	
		Page	Summary
		122	• Added IOBC to Function of the PRC1 bit in **Figure 9.1**: Deleted description of bits PRC0 and PRC1 from Note 1
			Chapter 10. Interrupts
		—	• Modified wording and enhanced description in this chapter
		126	• Modified description of Note 1 in **Figure 10.1**
		127	• Modified descriptions in the second paragraph in (5) of **10.2**
		129, 130, 137	• Modified description of jump operation in **10.5**, **Table 10.1**, and below **Figure 10.4**
		140	• Moved description of Note 1 to (2) of **10.6.4**
		141	• Modified description of Note 1 of **Table 10.7**
		143	• Modified descriptions in lines 4 to 5 and 7 to 8 of **10.8**
		150	• Corrected register symbol "IIOiE" in the last line of **10.13** to "IIOiIE"
			Chapter 11. Watchdog Timer
		—	• Modified wording and enhanced description in this chapter
		154	• Modified description in lines 4 to 6 of **11**; Corrected register symbol "WKD" in line 9 to "WDK"
			Chapter 12. DMAC
		—	• Modified wording and enhanced description in this chapter
		159	• Modified descriptions of timer- and UART-associated interrupt requests in "DMA request sources" in Table **12.1**; Modified description "more than 00000001h" in "DMA transfer start-up" to "other than 00000000h"
		167	• Modified descriptions in **12.1**
			Chapter 13. DMAC II
		—	• Modified wording and enhanced description in this chapter
			• Modified expressions "calculation transfer" and "chained transfer" to "calculation result transfer" and "chain transfer", respectively
		173	• Modified description of chain transfer in **Table 13.1**; Corrected source address "FFFFFFFh" in Note 1 to "FFFFFFFFh"
		175, 176	• Changed expression "DMA II transfer complete interrupt vector address" in lines 3 to 4 and the seventh bullet point of **13.1.2** and Figure **13.2** to "jump address for the DMA II transfer complete interrupt handler"
		175, 178	• Modified expression "interrupt vector" in **Figure 13.2** and line 1 of **13.1.4** to "interrupt vector space"
		176	• Changed expression "jump address" in the seventh bullet point of **13.1.2** to "start address"
		177	• Changed bit name "Transfer Number Set Bit" in **Figure 13.3** to "Number of Transfers Setting Bit"
		181	• Modified descriptions in **Figure 13.5**
			Chapter 14. Programmable I/O Port
		—	• Modified wording and enhanced description in this chapter
			Chapter 15. Timers
		—	• Modified wording and enhanced description in this chapter
		187	• Modified description for one-shot timer mode in **15.1**

Rev.	Date	Description	
		Page	Summary
		192	• Corrected typos "b2 b3", "b4 b5", and "b6 b7" in **Figure 15.9** to "b3 b2", "b5 b4", and "b7 b6", respectively
		198	• Corrected bit symbols "TAiTGH and TAiTGL" in Note 5 of **Figure 15.12** to "TAjTGH and TAjTGL"
		199	• Corrected pin name "INT2" in **Figures 15.13 and 15.14** to "$\overline{INT2}$"
		203	• Corrected a typo "TAiS" in Function of MR2 bit in **Figure 15.16** to "TAiOS"
		213	• Corrected bit symbol "TBjS" and register symbol "TBjMR" in Note 2 of **Table 15.8** to "TBiS" and "TBiMR", respectively
		218	• Modified description "TBjS bit in the TBjMR register" in the first bullet point of **15.3.3.2** to "TBjS bit in the TABSR or TBSR register"
			Chapter 16. Three-phase Motor Control Timers
		—	• Modified wording and enhanced description in this chapter
		222	• Corrected "Bits INV00 to INV02 and INV06" in Note 1 of **Figure 16.3** to "this register"
		229	• Deleted "The sum of setting values for registers TAi and TAi1 should be identical to the setting value of the TB2 register in this mode." from **16.3**; Added "TA4M" to line 9
		235	• Corrected register symbol "INV1" in Note 2 of **Figure 16.18** to "INVC1"
			Chapter 17. Serial Interface
		—	• Modified wording and enhanced description in this chapter
			• Modified description "restart condition" to "repeated START condition"
		243, 244	• Changed bit name "CTS Disable Bit" in **Figures 17.5 and 17.6** to "CTS Function Disable Bit"
		245	• Changed "UiTB register" in Function of the UiIRS bit in **Figure 17.7** to "Transmit buffer"; Modified bit name "Logical Inversion Select Bit" to "Logic Inversion Select Bit"
		247	• Modified bit name "Clock Synchronous Bit" in **Figure 17.11** to "Clock Synchronization Bit"
		248	• Modified "UiBRG count source" in Function of DL2 to DL0 in **Figure 17.12** to "baud rate generator count source"
		255	• Corrected bit symbol "UiRS" in **Figure 17.18** to "UiIRS"
		263, 264	• Corrected explanation for the UiIRS bit in **Figures 17.23 and 17.24**
		272	• Divided **Table 17.11** into Tables 17.11 and 17.12
			Chapter 18. A/D Converter
		—	• Modified wording and enhanced description in this chapter
		295	• Corrected "DMA" in Note 4 of **Figure 18.8** to "DMAC"
		297, 299, 300	• Modified "DMA" in the first bullet point in "Reading A/D converted result" of **Tables 18.3, 18.5, and 18.6** to "DMAC"
		300	• Modified description of the number of prioritized pins in line 1 of **18.1.5** and Function in **Table 18.6**
			Chapter 19. D/A Converter
		—	• Modified wording and enhanced description in this chapter

Rev.	Date	Description	
		Page	Summary
			Chapter 20. CRC Calculator
		—	• Modified wording and enhanced description in this chapter
		312	• Modified **Figure 20.1**
			Chapter 21. X-Y Conversion
		—	• Modified wording and enhanced description in this chapter
			Chapter 22. Intelligent I/O
		—	• Modified wording and enhanced description in this chapter
		324	• Modified Note 2 in **Figure 22.5**
		334	• Added "($\overline{INT0}$ or $\overline{INT1}$)" to the second bullet point for "Reset conditions" in **Table 22.2**; Changed description of the timer counter to start decrementing in the first bullet point of "Other functions"
		345, 347, 350	• Modified "Input to the IIOi_j pin" in **Figures 22.24 to 22.26** to "IIOi_j pin"
		348	• Divided **Table 22.9** into **Tables 22.9 and 22.10**
			Chapter 23. Serial Bus Interface
		—	• Modified wording and enhanced description in this chapter
		369	• Added description "with bits CKS2 to CKS0" to the first paragraph of (1) in **23.1.1**
		383	• Corrected bit symbol "MSL" in line 14 of **23.1.7** to "MLS"
			Chapter 24. LIN
		—	• Modified wording and enhanced description in this chapter
			Chapter 25. CAN Module
		—	• Modified wording and enhanced description in this chapter
		431	• Modified RBOC bit name in **Figure 25.2** to "Forced Recovery From Bus-off Bit"; Modified its function description
		438	• Modified descriptions in **25.1.4.1 and 25.1.4.2**
		448	• Modified description "fCAN (CAN system clock)" in **25.1.9.5** to "peripheral bus clock"
		451	• Modified description "fCAN" in **25.1.10.3** to "peripheral bus clock"
		457	• Changed description of b7 in **Figure 25.17** to "No register bit; the read value is 0"
		461	• Changed description of b6-b5 in **Figure 25.19** to "No register bits; the read value is 0"
		469	• Modified description in **25.1.20.8**
		478	• Added Note 3 to **Figure 25.34**
		480	• Corrected description "the completion of the first transmission" in Note 1 of **Table 25.9** to "the completion of the first message transmission"; Added descriptions to Note 2, Note 3, and Note 4
		490	• Moved "(j = 0 to 31)" and "(k = 0 to 7)" in **Figure 25.42** to its figure title
		492- 494	• Moved "(j = 0 to 31)" in **Figures 25.43 to 25.45** to their figure titles
			Chapter 26. I/O Pins
		—	• Modified wording and enhanced description in this chapter
		496	• Modified descriptions in the third paragraph below **Figure 26.1**
		502	• Corrected description "PD3_i register" in line 4 below **Figure 26.6** to "PD3_i bit"

Rev.	Date	Description	
		Page	Summary
			Chapter 27. Flash Memory
		—	• Modified wording and enhanced description in this chapter
		542	• Modified description in Note 2 of **Table 27.12**
		556	• Modified description in the first bullet point of **27.6.8**
			Chapter 28. E²PROM Emulation Data Flash
		—	• Modified wording and enhanced description in this chapter
			Chapter 29. Electrical Characteristics
		—	• Modified wording and enhanced description in this chapter
		573, 574	• Changed expressions "Programming and erasure endurance" in **Table 29.8** and "Programming and erasure endurance of flash memory" in **Table 29.9** to "Program/erase cycles"; Changed its unit "times" to "Cycles"
		580, 591	• Modified description "Drive power" in **Tables 29.18 and 29.38** to "Drive strength"
			Chapter 30. Usage Notes
		—	• Modified wording and enhanced description in this chapter
		604, 605	• Changed the order of **Tables 30.1 and 30.2**
		611	• Modified description "TBjS bit in the TBjMR register" in the first bullet point of **30.6.3.2** to "TBjS bit in the TABSR or TBSR register"
		613	• Modified description "restart condition" in **30.8.3** to "repeated START condition"
		619	• Modified description in the first bullet point of **30.11.8**
